Redundant recipes

- Recipe for baking **20** cookies:
 - Mix the following ingredients in a bowl:
 - **4** cups flour
 - **1** cup butter
 - **1** cup sugar
 - **2** eggs
 - **40** pounds chocolate chips ...
 - Place on sheet and Bake for about **10** minutes.
- Recipe for baking **40** cookies:
 - Mix the following ingredients in a bowl:
 - **8** cups flour
 - **2** cups butter
 - **2** cups sugar
 - **4** eggs
 - **80** pounds chocolate chips ...
 - Place on sheet and Bake for about **10** minutes.

Parameterized recipe

- Recipe for baking **20** cookies:
 - Mix the following ingredients in a bowl:
 - **4** cups flour
 - **1** cup sugar
 - **2** eggs
 - ...
- Recipe for baking **N** cookies:
 - Mix the following ingredients in a bowl:
 - **N/5** cups flour
 - **N/20** cups butter
 - **N/20** cups sugar
 - **N/10** eggs
 - **2N** bags chocolate chips ...
 - Place on sheet and Bake for about 10 minutes.
- **parameter:** A value that distinguishes similar tasks.

Redundant figures

- Consider the task of printing the following lines/boxes:

* *

* *

* *

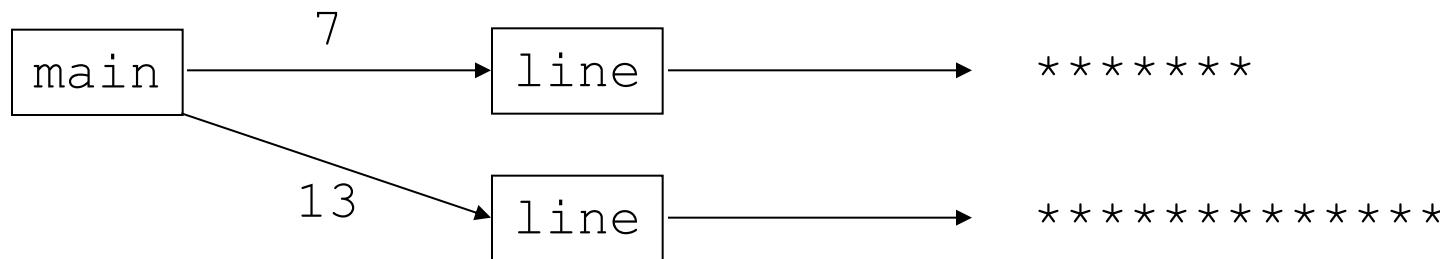

A redundant solution

```
public class Stars1 {  
    public static void main(String[] args) {  
        lineOf13();  
        lineOf7();  
        lineOf35();  
        box10x3();  
        box5x4();  
    }  
  
    public static void lineOf13() {  
        for (int i = 1; i <= 13; i++) {  
            System.out.print("*");  
        }  
        System.out.println();  
    }  
  
    public static void lineOf7() {  
        for (int i = 1; i <= 7; i++) {  
            System.out.print("*");  
        }  
        System.out.println();  
    }  
  
    public static void lineOf35() {  
        for (int i = 1; i <= 35; i++) {  
            System.out.print("*");  
        }  
        System.out.println();  
    }  
    ...  
}
```

- This code is redundant.
- Would variables help?
Would constants help?
- What is a better solution?
 - line - A method to draw a line of any number of stars.
 - box - A method to draw a box of any size.

Parameterization

- **parameter:** A value passed to a method by its caller.
 - Instead of `lineOf7`, `lineOf13`, write `line` to draw any length.
 - When *declaring* the method, we will state that it requires a parameter for the number of stars.
 - When *calling* the method, we will specify how many stars to draw.

Declaring a parameter

Stating that a method requires a parameter in order to run

```
public static void name ( type name ) {  
    statement(s);  
}
```

- Example:

```
public static void sayPassword(int code) {  
    System.out.println("The password is: " +  
        code);  
}
```

- When `sayPassword` is called, the caller must specify the integer code to print.

Passing a parameter

Calling a method and specifying values for its parameters

name (expression) ;

- Example:

```
public static void main(String[] args) {  
    sayPassword(42);  
    sayPassword(12345);  
}
```

Output:

```
The password is 42  
The password is 12345
```

Parameters and loops

- A parameter can guide the number of repetitions of a loop.

```
public static void main(String[] args) {  
    chant(3);  
}
```

```
public static void chant(int times) {  
    for (int i = 1; i <= times; i++) {  
        System.out.println("Just a salad...");  
    }  
}
```

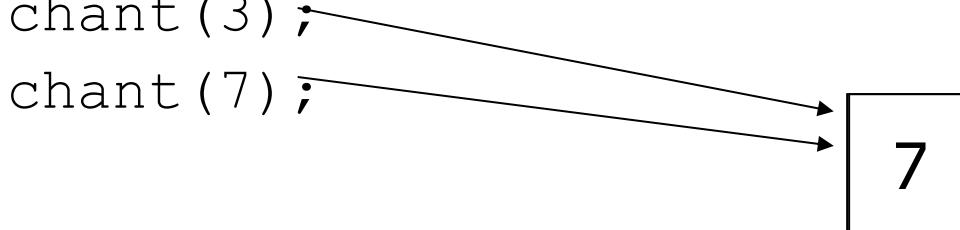

Output:

```
Just a salad...  
Just a salad...  
Just a salad...
```

How parameters are passed

- When the method is called:
 - The value is stored into the parameter variable.
 - The method's code executes using that value.

```
public static void main(String[] args) {  
    chant(3);  
    chant(7);  
}
```

A diagram illustrating parameter passing by value. Two arrows point from the integer literals 3 and 7 in the main method call to a single rectangular box containing the number 7. This visualizes how each argument is copied into a local variable (parameter) within the chant method, and both calls to chant receive different copies of the value 7.

```
public static void chant(int times) {  
    for (int i = 1; i <= times; i++) {  
        System.out.println("Just a salad...");  
    }  
}
```

Common errors

- If a method accepts a parameter, it is illegal to call it without passing any value for that parameter.

```
chant();      // ERROR: parameter value required
```

- The value passed to a method must be of the correct type.

```
chant(3.7);    // ERROR: must be of type int
```

- Exercise: Change the Stars program to use a parameterized method for drawing lines of stars.

Stars solution

```
// Prints several lines of stars.  
// Uses a parameterized method to remove redundancy.  
public class Stars2 {  
    public static void main(String[] args) {  
        line(13);  
        line(7);  
        line(35);  
    }  
  
    // Prints the given number of stars plus a line break.  
    public static void line(int count) {  
        for (int i = 1; i <= count; i++) {  
            System.out.print("*");  
        }  
        System.out.println();  
    }  
}
```

Multiple parameters

- A method can accept multiple parameters. (separate by ,)
 - When calling it, you must pass values for each parameter.
- Declaration:

```
public static void name (type name, ..., type name) {  
    statement(s);  
}
```

- Call:
methodName (**value**, **value**, ..., **value**);

Multiple params example

```
public static void main(String[] args) {  
    printNumber(4, 9);  
    printNumber(17, 6);  
    printNumber(8, 0);  
    printNumber(0, 8);  
}  
  
public static void printNumber(int number, int count) {  
    for (int i = 1; i <= count; i++) {  
        System.out.print(number);  
    }  
    System.out.println();  
}
```

Output:

```
44444444  
171717171717  
00000000
```

- Modify the Stars program to draw boxes with parameters.

Stars solution

```
// Prints several lines and boxes made of stars.  
// Third version with multiple parameterized methods.  
  
public class Stars3 {  
    public static void main(String[] args) {  
        line(13);  
        line(7);  
        line(35);  
        System.out.println();  
        box(10, 3);  
        box(5, 4);  
        box(20, 7);  
    }  
  
    // Prints the given number of stars plus a line break.  
    public static void line(int count) {  
        for (int i = 1; i <= count; i++) {  
            System.out.print("*");  
        }  
        System.out.println();  
    }  
    ...  
}
```

Stars solution, cont'd.

...

```
// Prints a box of stars of the given size.  
public static void box(int width, int height) {  
    line(width);  
  
    for (int line = 1; line <= height - 2; line++) {  
        System.out.print("*");  
        for (int space = 1; space <= width - 2; space++) {  
            System.out.print(" ");  
        }  
        System.out.println("*");  
    }  
  
    line(width);  
}  
}
```

Value semantics

- **value semantics:** When primitive variables (`int`, `double`) are passed as parameters, their values are copied.
 - Modifying the parameter will not affect the variable passed in.

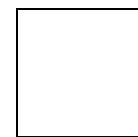

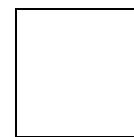

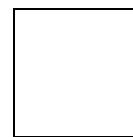

```
public static void strange(int x) {  
    x = x + 1;  
    System.out.println("1. x = " + x);  
}
```

```
public static void main(String[] args) {  
    int x = 23;  
    strange(x);  
    System.out.println("2. x = " + x);  
    ...  
}
```

Output:
1. x = 24
2. x = 23

"Parameter Mystery" problem

```
public class ParameterMystery {  
    public static void main(String[] args) {  
        int x = 9;  
        int y = 2;  
        int z = 5;  
  
        mystery(z, y, x);  
  
        mystery(y, x, z);  
    }  
}
```

```
public static void mystery(int x, int z, int y) {  
    System.out.println(z + " and " + (y - x));  
}  
}
```

Strings

- **string**: A sequence of text characters.

```
String name = "text";
```

```
String name = expression;
```

- Examples:

```
String name = "Marla Singer";
```

```
int x = 3;
```

```
int y = 5;
```

```
String point = "(" + x + ", " + y + ")";
```

Strings as parameters

```
public class StringParameters {  
    public static void main(String[] args) {  
        sayHello("Marty");  
  
        String teacher = "Bictolia";  
        sayHello(teacher);  
    }  
  
    public static void sayHello(String name) {  
        System.out.println("Welcome, " + name);  
    }  
}
```

Output:

```
Welcome, Marty  
Welcome, Bictolia
```

- Modify the Stars program to use string parameters. Use a method named repeat that prints a string many times.

Stars solution

```
// Prints several lines and boxes made of stars.  
// Fourth version with String parameters.  
  
public class Stars4 {  
    public static void main(String[] args) {  
        line(13);  
        line(7);  
        line(35);  
        System.out.println();  
        box(10, 3);  
        box(5, 4);  
        box(20, 7);  
    }  
  
    // Prints the given number of stars plus a line break.  
    public static void line(int count) {  
        repeat("*", count);  
        System.out.println();  
    }  
  
    ...
```

Stars solution, cont'd.

...

```
// Prints a box of stars of the given size.  
public static void box(int width, int height) {  
    line(width);  
  
    for (int line = 1; line <= height - 2; line++) {  
        System.out.print("*");  
        repeat(" ", width - 2);  
        System.out.println("*");  
    }  
  
    line(width);  
}  
  
// Prints the given String the given number of times.  
public static void repeat(String s, int times) {  
    for (int i = 1; i <= times; i++) {  
        System.out.print(s);  
    }  
}
```

Return values

Java's Math class

Method name	Description
Math.abs (<i>value</i>)	absolute value
Math.ceil (<i>value</i>)	rounds up
Math.floor (<i>value</i>)	rounds down
Math.log10 (<i>value</i>)	logarithm, base 10
Math.max (<i>value1, value2</i>)	larger of two values
Math.min (<i>value1, value2</i>)	smaller of two values
Math.pow (<i>base, exp</i>)	<i>base</i> to the <i>exp</i> power
Math.random ()	random double between 0 and 1
Math.round (<i>value</i>)	nearest whole number
Math.sqrt (<i>value</i>)	square root
Math.sin (<i>value</i>)	sine/cosine/tangent of an angle in radians
Math.cos (<i>value</i>)	
Math.tan (<i>value</i>)	
Math.toDegrees (<i>value</i>)	convert degrees to radians and back
Math.toRadians (<i>value</i>)	

Constant	Description
Math.E	2.7182818...
Math.PI	3.1415926...

Calling Math methods

`Math.methodName(parameters)`

- Examples:

```
double squareRoot = Math.sqrt(121.0);  
System.out.println(squareRoot); // 11.0
```

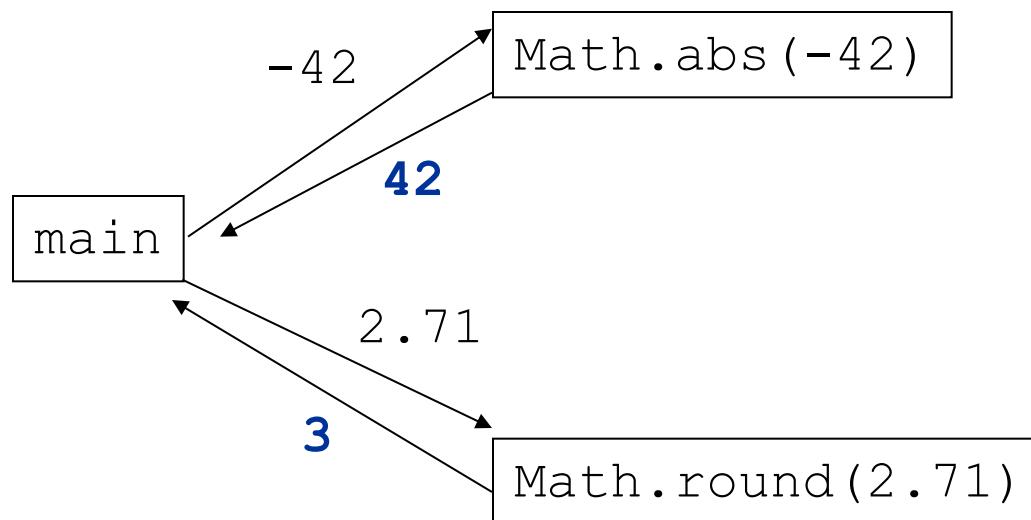

```
int absoluteValue = Math.abs(-50);  
System.out.println(absoluteValue); // 50
```

```
System.out.println(Math.min(3, 7) + 2); // 5
```

- The Math methods do not print to the console.
 - Each method produces ("returns") a numeric result.
 - The results are used as expressions (printed, stored, etc.).

Return

- **return:** To send out a value as the result of a method.
 - The opposite of a parameter:
 - Parameters send information *in* from the caller to the method.
 - Return values send information *out* from a method to its caller.
 - A call to the method can be used as part of an expression.

Math questions

- Evaluate the following expressions:
 - `Math.abs(-1.23)`
 - `Math.pow(3, 2)`
 - `Math.pow(10, -2)`
 - `Math.sqrt(121.0) - Math.sqrt(256.0)`
 - `Math.round(Math.PI) + Math.round(Math.E)`
 - `Math.ceil(6.022) + Math.floor(15.9994)`
 - `Math.abs(Math.min(-3, -5))`
- `Math.max` and `Math.min` can be used to bound numbers.
Consider an `int` variable named `age`.
 - What statement would replace negative ages with 0?
 - What statement would cap the maximum age to 40?

Quirks of real numbers

- Some Math methods return double or other non-int types.

```
int x = Math.pow(10, 3);    // ERROR: incompat. types
```

- Some double values print poorly (too many digits).

```
double result = 1.0 / 3.0;  
System.out.println(result);    // 0.3333333333333333
```

- The computer represents doubles in an imprecise way.

```
System.out.println(0.1 + 0.2);
```

- Instead of 0.3, the output is 0.3000000000000004

Type casting

- **type cast:** A conversion from one type to another.
 - To promote an `int` into a `double` to get exact division from `/`
 - To truncate a `double` from a real number to an integer
- Syntax:
(type) expression

Examples:

```
double result = (double) 19 / 5;           // 3.8
int result2 = (int) result;                 // 3
int x = (int) Math.pow(10, 3);             // 1000
```

More about type casting

- Type casting has high precedence and only casts the item immediately next to it.
 - `double x = (double) 1 + 1 / 2; // 1`
 - `double y = 1 + (double) 1 / 2; // 1.5`
- You can use parentheses to force evaluation order.
 - `double average = (double) (a + b + c) / 3;`
- A conversion to double can be achieved in other ways.
 - `double average = 1.0 * (a + b + c) / 3;`

Returning a value

```
public static type name(parameters) {  
    statements;  
    ...  
    return expression;  
}
```

- Example:

```
// Returns the slope of the line between the given points.  
public static double slope(int x1, int y1, int x2, int y2) {  
    double dy = y2 - y1;  
    double dx = x2 - x1;  
    return dy / dx;  
}
```

- slope(1, 3, 5, 11) returns 2.0

Return examples

```
// Converts degrees Fahrenheit to Celsius.
```

```
public static double fToC(double degreesF) {  
    double degreesC = 5.0 / 9.0 * (degreesF - 32);  
    return degreesC;  
}
```

```
// Computes triangle hypotenuse length given its side lengths.
```

```
public static double hypotenuse(int a, int b) {  
    double c = Math.sqrt(a * a + b * b);  
    return c;  
}
```

- You can shorten the examples by returning an expression:

```
public static double fToC(double degreesF) {  
    return 5.0 / 9.0 * (degreesF - 32);  
}
```

Common error: Not storing

- Many students incorrectly think that a `return` statement sends a variable's name back to the calling method.

```
public static void main(String[] args) {  
    slope(0, 0, 6, 3);  
    System.out.println("The slope is " + result); // ERROR:  
} // result not defined
```

```
public static double slope(int x1, int x2, int y1, int y2) {  
    double dy = y2 - y1;  
    double dx = x2 - x1;  
    double result = dy / dx;  
    return result;  
}
```

Fixing the common error

- Instead, returning sends the variable's *value* back.
 - The returned value must be stored into a variable or used in an expression to be useful to the caller.

```
public static void main(String[] args) {  
    double s = slope(0, 0, 6, 3);  
    System.out.println("The slope is " + s);  
}
```

```
public static double slope(int x1, int x2, int y1, int y2) {  
    double dy = y2 - y1;  
    double dx = x2 - x1;  
    double result = dy / dx;  
    return result;  
}
```

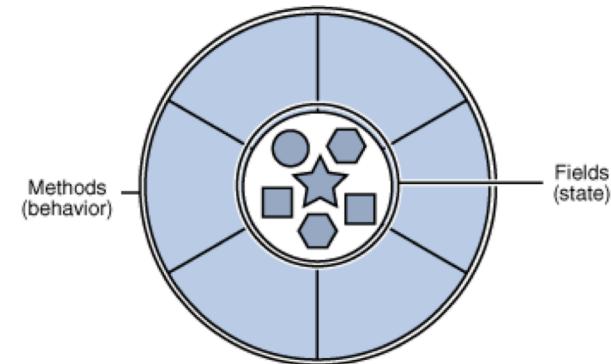

Objects and Classes; Strings

Classes and objects

- **class:** A program entity that represents either:
 1. A program / module, or
 2. A type of objects.
 - A class is a blueprint or template for constructing objects.
 - Example: The `DrawingPanel` class (type) is a template for creating many `DrawingPanel` objects (windows).
 - Java has 1000s of classes. Later (Ch.8) we will write our own.
- **object:** An entity that combines data and behavior.
 - **object-oriented programming (OOP):** Programs that perform their behavior as interactions between objects.

Objects

- **object:** An entity that contains data and behavior.
 - *data:* variables inside the object
 - *behavior:* methods inside the object
 - You interact with the methods; the data is hidden in the object.

- Constructing (creating) an object:
Type objectName = new Type (parameters) ;
- Calling an object's method:
objectName.methodName (parameters) ;

Blueprint analogy

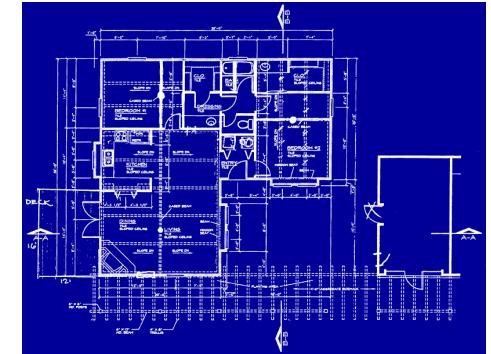

iPod blueprint/factory

state:

current song
volume
battery life

behavior:

power on/off
change station/song
change volume
choose random song

creates

iPod #1**state:**

song = "1,000,000 Miles"
volume = 17
battery life = 2.5 hrs

behavior:

power on/off
change station/song
change volume
choose random song

**iPod #2****state:**

song = "Letting You"
volume = 9
battery life = 3.41 hrs

behavior:

power on/off
change station/song
change volume
choose random song

**iPod #3****state:**

song = "Discipline"
volume = 24
battery life = 1.8 hrs

behavior:

power on/off
change station/song
change volume
choose random song

Strings

- **string**: An object storing a sequence of text characters.
 - Unlike most other objects, a `String` is not created with `new`.

```
String name = "text";
```

```
String name = expression;
```

- Examples:

```
String name = "Marla Singer";
```

```
int x = 3;
```

```
int y = 5;
```

```
String point = "(" + x + ", " + y + ")";
```

Indexes

- Characters of a string are numbered with 0-based *indexes*:

```
String name = "woodpile";
```

index	0	1	2	3	4	5	6	7
character	w	o	o	d	p	i	l	e

- First character's index : 0
- Last character's index : 1 less than the string's length
- The individual characters are values of type `char` (seen later)

String methods

Method name	Description
indexOf (str)	index where the start of the given string appears in this string (-1 if not found)
length ()	number of characters in this string
substring (index1 , index2) or substring (index1)	the characters in this string from <i>index1</i> (inclusive) to <i>index2</i> (<u>exclusive</u>); if <i>index2</i> is omitted, grabs till end of string
toLowerCase ()	a new string with all lowercase letters
toUpperCase ()	a new string with all uppercase letters

- These methods are called using the dot notation:

```
String gangsta = "Dr. Dre";  
System.out.println(gangsta.length()); // 7
```

String method examples

```
// index      012345678901
String s1 = "Stuart Reges";
String s2 = "Marty Stepp";

System.out.println(s1.length());           // 12
System.out.println(s1.indexOf("e"));       // 8
System.out.println(s1.substring(7, 10));   // "Reg"

String s3 = s2.substring(1, 7);
System.out.println(s3.toLowerCase());      // "arty s"
```

- Given the following string:

```
// index      0123456789012345678901
String book = "Building Java Programs";
```

- How would you extract the word "Java" ?

Modifying strings

- Methods like `substring` and `toLowerCase` build and return a new string, rather than modifying the current string.

```
String s = "lil bow wow";
s.toUpperCase();
System.out.println(s);    // lil bow wow
```

- To modify a variable's value, you must reassign it:

```
String s = "lil bow wow";
s = s.toUpperCase();
System.out.println(s);    // LIL BOW WOW
```

Interactive Programs with Scanner

Input and System.in

- **interactive program:** Reads input from the console.
 - While the program runs, it asks the user to type input.
 - The input typed by the user is stored in variables in the code.
 - Can be tricky; users are unpredictable and misbehave.
 - But interactive programs have more interesting behavior.
- **Scanner:** An object that can read input from many sources.
 - Communicates with System.in (the opposite of System.out)
 - Can also read from files (Ch. 6), web sites, databases, ...

Scanner syntax

- The Scanner class is found in the java.util package.

```
import java.util.*;      // so you can use Scanner
```

- Constructing a Scanner object to read console input:

```
Scanner name = new Scanner(System.in);
```

- Example:

```
Scanner console = new Scanner(System.in);
```

Scanner methods

Method	Description
nextInt ()	reads an int from the user and returns it
nextDouble ()	reads a double from the user
next ()	reads a one-word String from the user
nextLine ()	reads a one-line String from the user

- Each method waits until the user presses Enter.
- The value typed by the user is returned.

```
System.out.print("How old are you? "); // prompt  
int age = console.nextInt();  
System.out.println("You typed " + age);
```

- **prompt:** A message telling the user what input to type.

Scanner example

```
import java.util.*; // so that I can use Scanner  
  
public class UserInputExample {  
    public static void main(String[] args) {  
        Scanner console = new Scanner(System.in);  
  
        → System.out.print("How old are you? "); age [29]  
        → int age = console.nextInt();  
              
        → int years = 65 - age; years [36]  
        System.out.println(years + " years to retirement!");  
    }  
}
```

- Console (user input underlined):

How old are you? 29
36 years until retirement!

Scanner example 2

```
import java.util.*;    // so that I can use Scanner

public class ScannerMultiply {
    public static void main(String[] args) {
        Scanner console = new Scanner(System.in);

        System.out.print("Please type two numbers: ");
        int num1 = console.nextInt();
        int num2 = console.nextInt();

        int product = num1 * num2;
        System.out.println("The product is " + product);
    }
}
```

- Output (user input underlined):

Please type two numbers: 8 6
The product is 48

- The Scanner can read multiple values from one line.

Input tokens

- **token**: A unit of user input, as read by the Scanner.
 - Tokens are separated by *whitespace* (spaces, tabs, new lines).
 - How many tokens appear on the following line of input?

```
23 John Smith 42.0 "Hello world" $2.50 " 19"
```

- When a token is not the type you ask for, it crashes.

```
System.out.print("What is your age? ");
int age = console.nextInt();
```

Output:

```
What is your age? Timmy
java.util.InputMismatchException
    at java.util.Scanner.next(Unknown Source)
    at java.util.Scanner.nextInt(Unknown Source)
    ...

```

Strings as user input

- Scanner's next method reads a word of input as a String.

```
Scanner console = new Scanner(System.in);
System.out.print("What is your name? ");
String name = console.next();
name = name.toUpperCase();
System.out.println(name + " has " + name.length() +
    " letters and starts with " + name.substring(0, 1));
```

Output:

What is your name? Chamillionaire

CHAMILLIONAIRE has 14 letters and starts with C

- The nextLine method reads a line of input as a String.

```
System.out.print("What is your address? ");
String address = console.nextLine();
```

Strings question

- Write a program that outputs a person's "gangsta name."
 - first initial
 - *Diddy*
 - last name (all caps)
 - first name
 - *-izzle*

Example Output:

Type your name, playa: Marge Simpson

Your gangsta name is "M. Diddy SIMPSON Marge-izzle"

Strings answer

```
// This program prints your "gangsta" name.  
import java.util.*;  
  
public class GangstaName {  
    public static void main(String[] args) {  
        Scanner console = new Scanner(System.in);  
        System.out.print("Type your name, playa: ");  
        String name = console.nextLine();  
  
        // split name into first/last name and initials  
        String first = name.substring(0, name.indexOf(" "));  
        String last = name.substring(name.indexOf(" ") + 1);  
        last = last.toUpperCase();  
        String fInitial = first.substring(0, 1);  
  
        System.out.println("Your gangsta name is \"" + fInitial + ". Diddy " + last + " " + first + "-izzle\"");  
    }  
}
```
