

Polymorphism

Motivation

- Given the following:

```
Lawyer laura = new Lawyer();
```

```
Marketer mark = new Marketer();
```

- Write a program that will print out the salaries and the color of the vacation form for each employee.

Polymorphism

- A reference variable of type T can refer to an object of any subclass of T.

```
Employee person = new Lawyer();
```

- **polymorphism:** The ability for the same code to be used with several different types of objects and behave differently depending on the type of object used.

Dynamic (or Run-Time) Type and Static (or Compile-Time) Type

```
Employee person = new Lawyer();
```

- The variable person has two types:

- static type: Employee

- This is the type that the compiler uses to determine if statements are legal Java statements.
 - Therefore, any method called with the person variable must be declared in the Employee class (or else the compiler will complain).

- dynamic type: Lawyer

- This is the type that the Java virtual machine uses to execute code when the program is run.
 - Any method called with the person variable will execute the version of that method defined in the Lawyer class.

Properties of polymorphism

```
Employee person = new Lawyer();  
System.out.println(person.getSalary());           // 40000.0  
System.out.println(person.getVacationForm());    // "pink"
```

- You can call any method from Employee on the person variable, but not any method specific to Lawyer (such as sue).
- Once a method is called on the object, it behaves in its normal way (as a Lawyer, not as a normal Employee).

Polymorphism and parameters

```
public class EmployeeMain {  
    public static void main(String[] args) {  
        Lawyer laura = new Lawyer();  
        Marketer mark = new Marketer();  
        printInfo(laura);  
        printInfo(mark);  
    }  
  
    public static void printInfo(Employee empl) {  
        System.out.println("salary = " + empl.getSalary());  
        System.out.println("days = " + empl.getVacationDays());  
        System.out.println("form = " + empl.getVacationForm());  
        System.out.println();  
    }  
}
```

Output:

```
salary = 40000.0  
vacation days = 15  
vacation form = pink
```

```
salary = 50000.0  
vacation days = 10  
vacation form = yellow
```

Polymorphism and arrays

```
public class EmployeeMain2 {  
    public static void main(String[] args) {  
        Employee[] employees = { new Lawyer(), new Secretary(),  
                                new Marketer(), new LegalSecretary() };  
        for (int i = 0; i < employees.length; i++) {  
            System.out.println("salary = " + employees[i].getSalary());  
            System.out.println("vacation days = " +  
                               employees[i].getVacationDays());  
            System.out.println();  
        }  
    }  
}
```

Output:

```
salary = 40000.0  
vacation days = 15  
  
salary = 40000.0  
vacation days = 10  
  
salary = 50000.0  
vacation days = 10  
  
salary = 45000.0  
vacation days = 10
```

Exercise 1

- Assume that the following four classes have been declared:

```
public class Foo {  
    public void method1() {  
        System.out.println("foo 1");  
    }  
  
    public void method2() {  
        System.out.println("foo 2");  
    }  
  
    public String toString() {  
        return "foo";  
    }  
}  
  
public class Bar extends Foo {  
    public void method2() {  
        System.out.println("bar 2");  
    }  
}
```

```
public class Baz extends Foo {  
    public void method1() {  
        System.out.println("baz 1");  
    }  
  
    public String toString() {  
        return "baz";  
    }  
}  
  
public class Mumble extends Baz {  
    public void method2() {  
        System.out.println("mumble 2");  
    }  
}
```

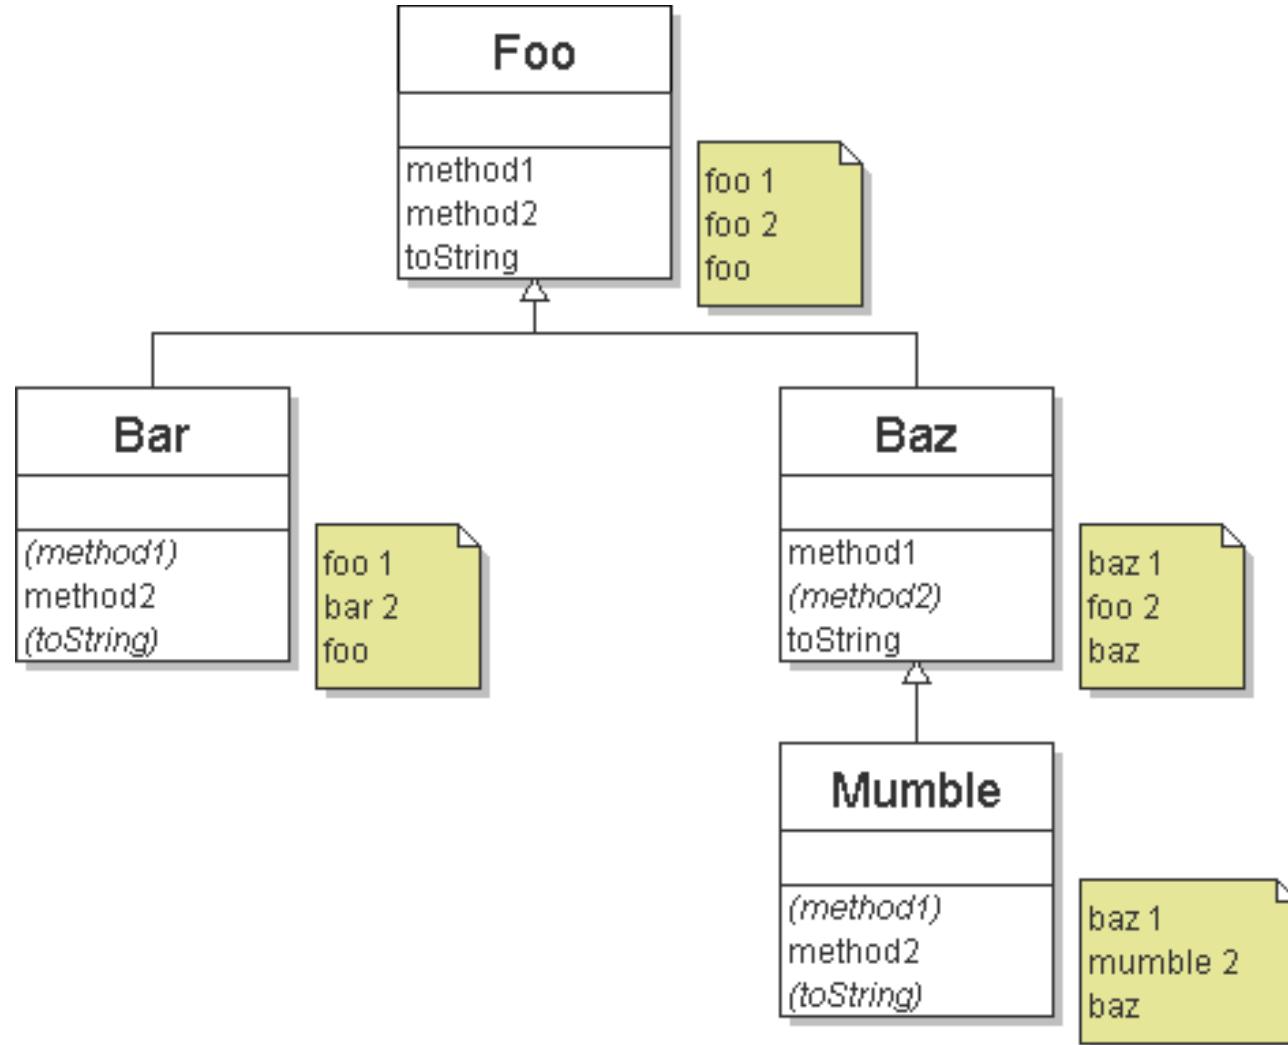

Exercise 1

- What would be the output of the following client code?

```
Foo[] pity = { new Baz(), new Bar(),
               new Mumble(), new Foo() } ;

for (int i = 0; i < pity.length; i++) {
    System.out.println(pity[i]);
    pity[i].method1();
    pity[i].method2();
    System.out.println();
}
```

Diagramming polymorphic code

```
public class Foo {  
    public void method1() {  
        System.out.println("foo 1");  
    }  
  
    public void method2() {  
        System.out.println("foo 2");  
    }  
  
    public String toString() {  
        return "foo";  
    }  
}  
  
public class Bar extends Foo {  
    public void method2() {  
        System.out.println("bar 2");  
    }  
}
```

```
Foo[] pity = { new Baz(),  
               new Bar(),  
               new Mumble(),  
               new Foo() };  
  
for (int i = 0; i < pity.length; i++) {  
    System.out.println(pity[i]);  
    pity[i].method1();  
    pity[i].method2();  
    System.out.println();  
}
```

```
public class Baz extends Foo {  
    public void method1() {  
        System.out.println("baz 1");  
    }  
  
    public String toString() {  
        return "baz";  
    }  
}  
  
public class Mumble extends Baz {  
    public void method2() {  
        System.out.println("mumble 2");  
    }  
}
```

Output:

Solution 1

- The code produces the following output:

```
baz  
baz 1  
foo 2
```

```
foo  
foo 1  
bar 2
```

```
baz  
baz 1  
mumble 2
```

```
foo  
foo 1  
foo 2
```

Exercise 2

- Assume that the following four classes have been declared:

```
public class Lamb extends Ham {  
    public void b() {  
        System.out.println("Lamb b");  
    }  
}  
  
public class Ham {  
    public void a() {  
        System.out.println("Ham a");  
    }  
  
    public void b() {  
        System.out.println("Ham b");  
    }  
  
    public String toString() {  
        return "Ham";  
    }  
}
```

```
public class Spam extends Yam {  
    public void a() {  
        System.out.println("Spam a");  
    }  
}  
  
public class Yam extends Lamb {  
    public void a() {  
        System.out.println("Yam a");  
    }  
  
    public String toString() {  
        return "Yam";  
    }  
}
```

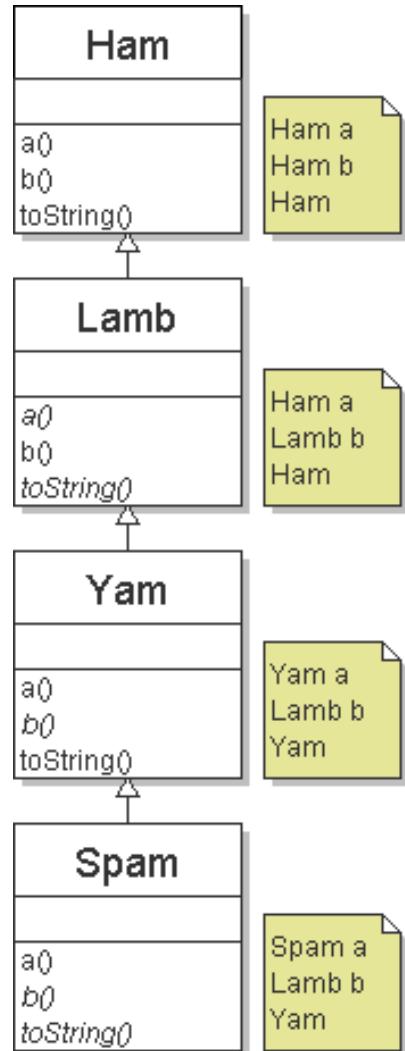

Exercise 2

- What would be the output of the following client code?

```
Ham[] food = { new Spam(), new Yam(),
               new Ham(), new Lamb() } ;

for (int i = 0; i < food.length; i++) {
    System.out.println(food[i]);
    food[i].a();
    food[i].b();
    System.out.println();
}
```

Diagramming polymorphic code

```
public class Lamb extends Ham {  
    public void b() {  
        System.out.println("Lamb b");  
    }  
}  
  
public class Ham {  
    public void a() {  
        System.out.println("Ham a");  
    }  
  
    public void b() {  
        System.out.println("Ham b");  
    }  
  
    public String toString() {  
        return "Ham";  
    }  
}
```

```
public class Spam extends Yam {  
    public void a() {  
        System.out.println("Spam a");  
    }  
}  
  
public class Yam extends Lamb {  
    public void a() {  
        System.out.println("Yam a");  
    }  
  
    public String toString() {  
        return "Yam";  
    }  
}
```

```
Ham[] food = { new Spam(),  
               new Yam(),  
               new Ham(),  
               new Lamb() };  
  
for (int i = 0; i < food.length;  
     i++) {  
    System.out.println(food[i]);  
    food[i].a();  
    food[i].b();  
    System.out.println();  
}
```

Output:

Solution 2

- The code produces the following output:

Yam
Spam a
Lamb b

Yam
Yam a
Lamb b

Ham
Ham a
Ham b

Ham
Ham a
Lamb b

Variable Shadowing

Something to avoid!!

Variable Shadowing:

Something to avoid!!

- Polymorphism applies to methods in Java
- *But not to fields!*

```
public class A {  
    int x = 1;  
  
    int method() { return 1; }  
}  
  
public class B extends A {  
    int x = 2;  
  
    int method() { return 2; }  
}
```

```
A a1 = new A();  
A a2 = new B();  
  
System.out.println(a1.method());  
// prints 1  
System.out.println(a2.method());  
// prints 2  
  
System.out.println(a1.x);  
// prints 1  
System.out.println(a2.x);  
// prints 1 still!
```

Variable Shadowing:

Something to avoid!!

■ Variable Shadowing:

- When a class extends another class and defines a field with the same name, each object of the subclass contains two fields with that name.
- The subclass's version of the field is said to *shadow* the superclass's version, making the superclass's version invisible within that class.
- This is called variable shadowing.

Variable Shadowing:

Something to avoid!!

Variable Shadowing and References

- If class B extends class A and both have a field of the same name, *references* to objects of type B can access one or the other of the fields.
- The version of the field that they reference depends on the type of the reference variable.

Variable Shadowing:

Something to avoid!!

```
public class A {  
    int x = 1;  
    int method() { return 1; }  
}  
  
public class B extends A {  
    int x = 2;  
    int method() { return 2; }  
}
```

```
A a1 = new A();  
A a2 = new B();  
  
System.out.println(a1.method());  
// prints 1  
System.out.println(a2.method());  
// prints 2  
  
System.out.println(a1.x);  
// prints 1  
System.out.println(a2.x);  
// prints 1 still!  
// because reference a2 has  
// compile-time type A.
```

Variable Shadowing:

Something to avoid!!

```
public class A {  
    int x = 1;  
    int method() { return 1; }  
}  
  
public class B extends A {  
    int x = 2;  
    int method() { return 2; }  
}
```

```
A a1 = new A();  
A a2 = new B();  
B b1 = (B)a2;  
  
System.out.println(a1.method());  
// prints 1  
System.out.println(a2.method());  
// prints 2  
  
System.out.println(a1.x);  
// prints 1  
System.out.println(a2.x);  
// prints 1 still!  
System.out.println(b1.x);  
// prints 2!  
// because b1 has static type B
```

Overriding vs. Variable Shadowing

Overriding	Variable Shadowing
Applies to methods	Applies to fields
If subclass overrides a superclass method, it <u>does not</u> inherit the superclass method.	If a subclass shadows a superclass field, it <u>does</u> inherit the superclass field, but shadows it.
The behavior of a method call depends on the dynamic (run-time) type of the object.	The behavior of a field access depends on the static (compile-time) type of the reference to the object.

Variable Shadowing:

Something to avoid!!

- By this time, hopefully you can see that variable shadowing on its own is not that all that complicated, no more than method overriding.
- But if you have to keep track of both method overriding and variable shadowing, then **variable shadowing is very confusing**
- In general, programmers try to avoid it, and they use method overriding all the time.

Exercise 3

- Assume that the following classes have been declared:

```
public class Ham {  
    int a = 0;  
    int b = 1;  
    public void a() {  
        System.out.println("Ham " + a);  
    }  
  
    public void b() {  
        System.out.println("Ham " + b);  
    }  
  
    public String toString() {  
        return "Ham " + a + " " + b;  
    }  
}
```

```
public class Spam extends Ham {  
    int a = 2;  
    public void a() {  
        System.out.println("Spam " + a);  
    }  
  
    public class Yam extends Spam {  
        int b = 3;  
        public void a() {  
            System.out.println("Yam " + a);  
        }  
  
        public void b() {  
            System.out.println("Yam " + b);  
        }  
    }  
}
```

Exercise 3

- What would be the output of the following client code?

```
Ham[] food = { new Spam(), new Yam(),
               new Ham() };

for (int i = 0; i < food.length; i++) {
    System.out.println(food[i]);
    food[i].a();
    food[i].b();
    System.out.println(food[i].a);
    System.out.println(food[i].b);
    System.out.println();
}
```

```
public class Ham {  
    int a = 0;  
    int b = 1;  
    public void a() {  
        System.out.println("Ham " + a);  
    }  
  
    public void b() {  
        System.out.println("Ham " + b);  
    }  
  
    public String toString() {  
        return "Ham " + a + " " + b;  
    }  
}
```

```
Ham[] food = { new Spam(),  
               new Yam(),  
               new Ham() };  
  
for (int i = 0;  
     i < food.length; i++) {  
    System.out.println(food[i]);  
    food[i].a();  
    food[i].b();  
  
    System.out.println(food[i].a);  
    System.out.println(food[i].b);  
}
```

```
public class Spam extends Ham {  
    int a = 2;  
    public void a() {  
        System.out.println("Spam " + a);  
    }  
  
    public class Yam extends Spam {  
        int b = 3;  
        public void a() {  
            System.out.println("Yam " + a);  
        }  
  
        public void b() {  
            System.out.println("Yam " + b);  
        }  
    }  
}
```

Output:
