# Chapter 3: Transport Layer

## our goals:

- understand principles behind transport layer services:
  - multiplexing, demultiplexing
  - reliable data transfer
- learn about Internet transport layer protocols:
  - UDP: connectionless transport
  - TCP: connection-oriented reliable transport
  - TCP congestion control

# Chapter 3 outline

3.1 transport-layer services

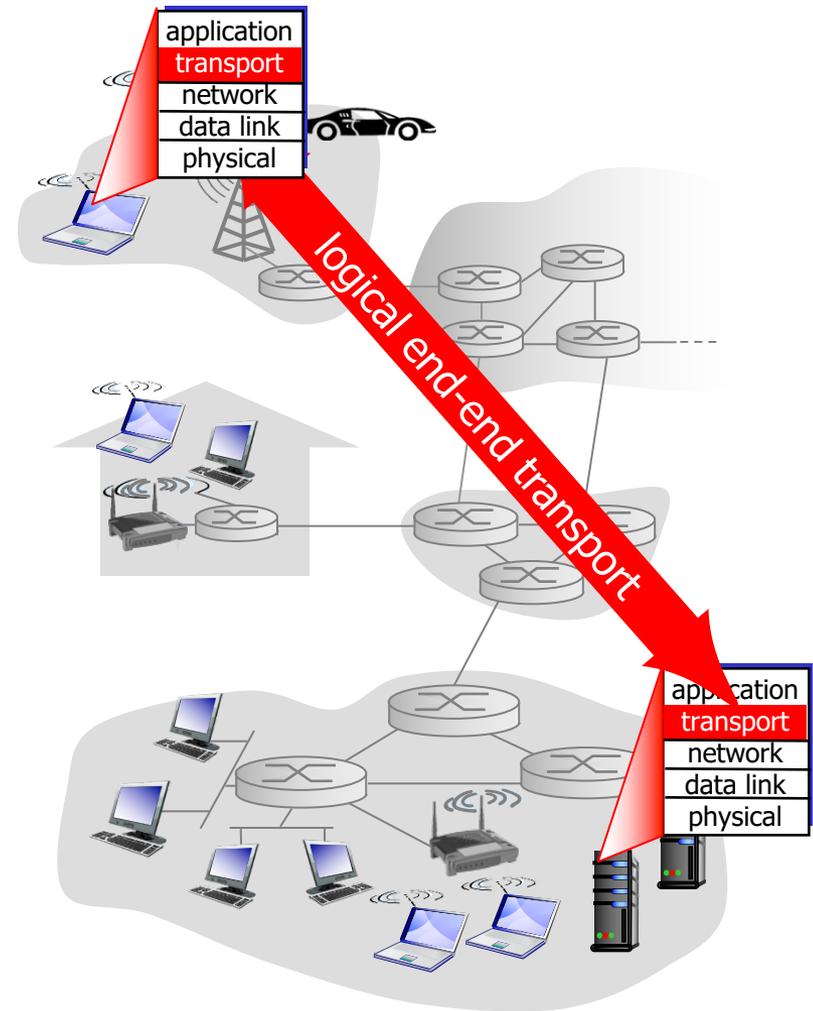

3.2 multiplexing and demultiplexing

3.3 connectionless transport: UDP

3.4 principles of reliable data transfer

# Transport services and protocols

- provide *logical communication* between app processes running on different hosts
- transport protocols run in end systems
  - send side: breaks app messages into *segments*, passes to network layer
  - rcv side: reassembles segments into messages, passes to app layer
- more than one transport protocol available to apps
  - Internet: TCP and UDP

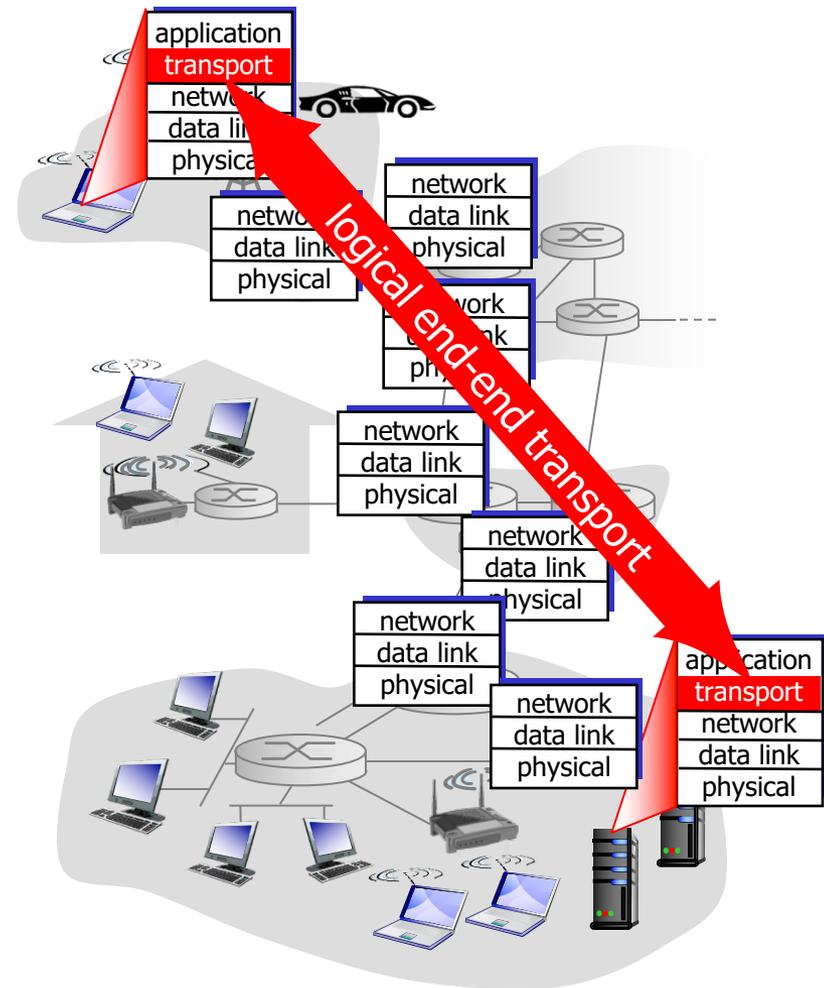

# Transport vs. network layer

- *network layer*: logical communication between hosts
- *transport layer*: logical communication between processes
  - relies on, enhances, network layer services

# Internet transport-layer protocols

- reliable, in-order delivery (TCP)
  - congestion control
  - flow control
  - connection setup
- unreliable, unordered delivery: UDP
  - no-frills extension of “best-effort” IP
- services not available:
  - delay guarantees
  - bandwidth guarantees

# Chapter 3 outline

3.1 transport-layer services

3.2 multiplexing and demultiplexing

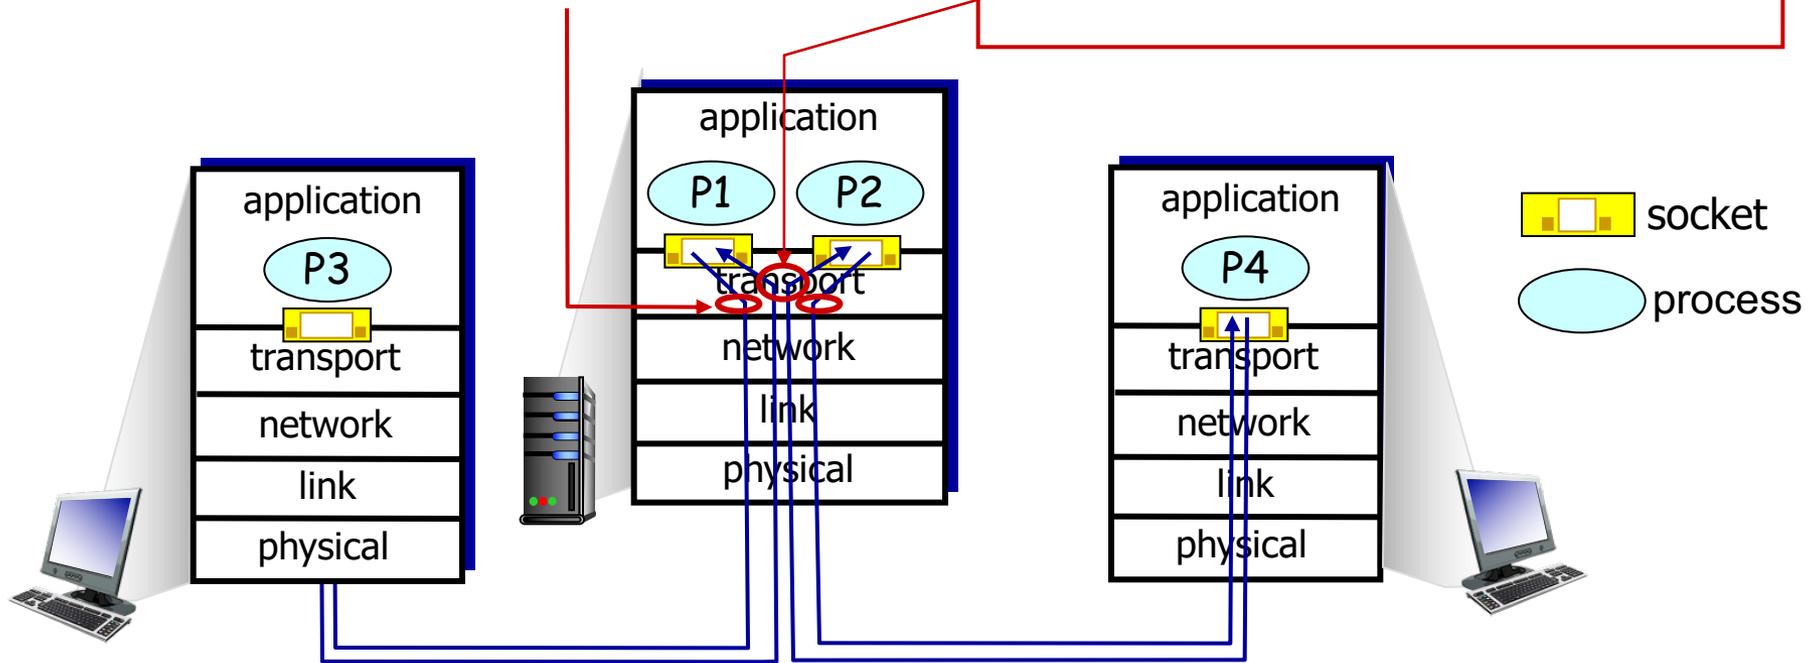

3.3 connectionless transport: UDP

3.4 principles of reliable data transfer

# Multiplexing/demultiplexing

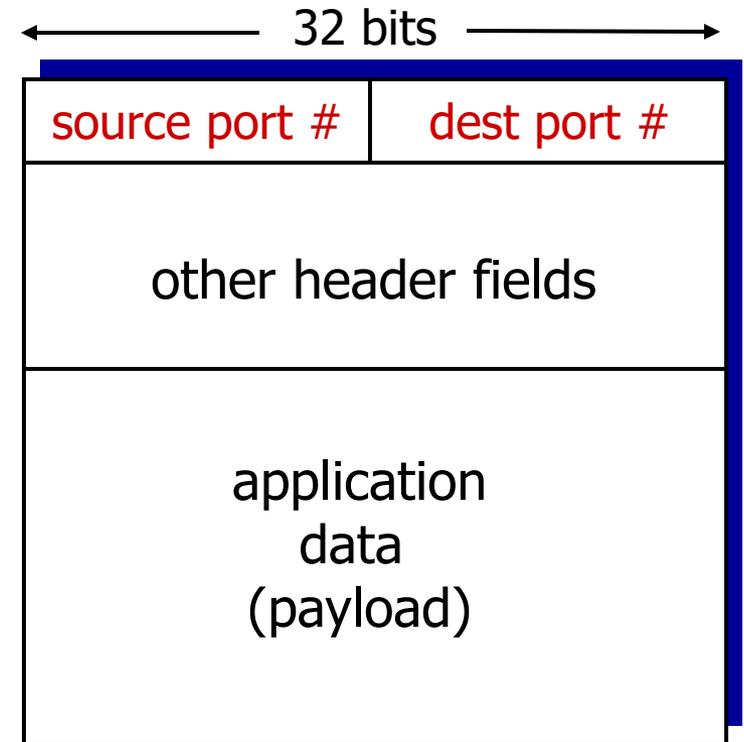

*multiplexing at sender:*  
handle data from multiple sockets, add transport header (later used for demultiplexing)

*demultiplexing at receiver:*  
use header info to deliver received segments to correct socket

# How demultiplexing works

- host receives IP datagrams
  - each datagram has source IP address, destination IP address
  - each datagram carries one transport-layer segment
  - each segment has source, destination port number
- host uses *IP addresses & port numbers* to direct segment to appropriate socket

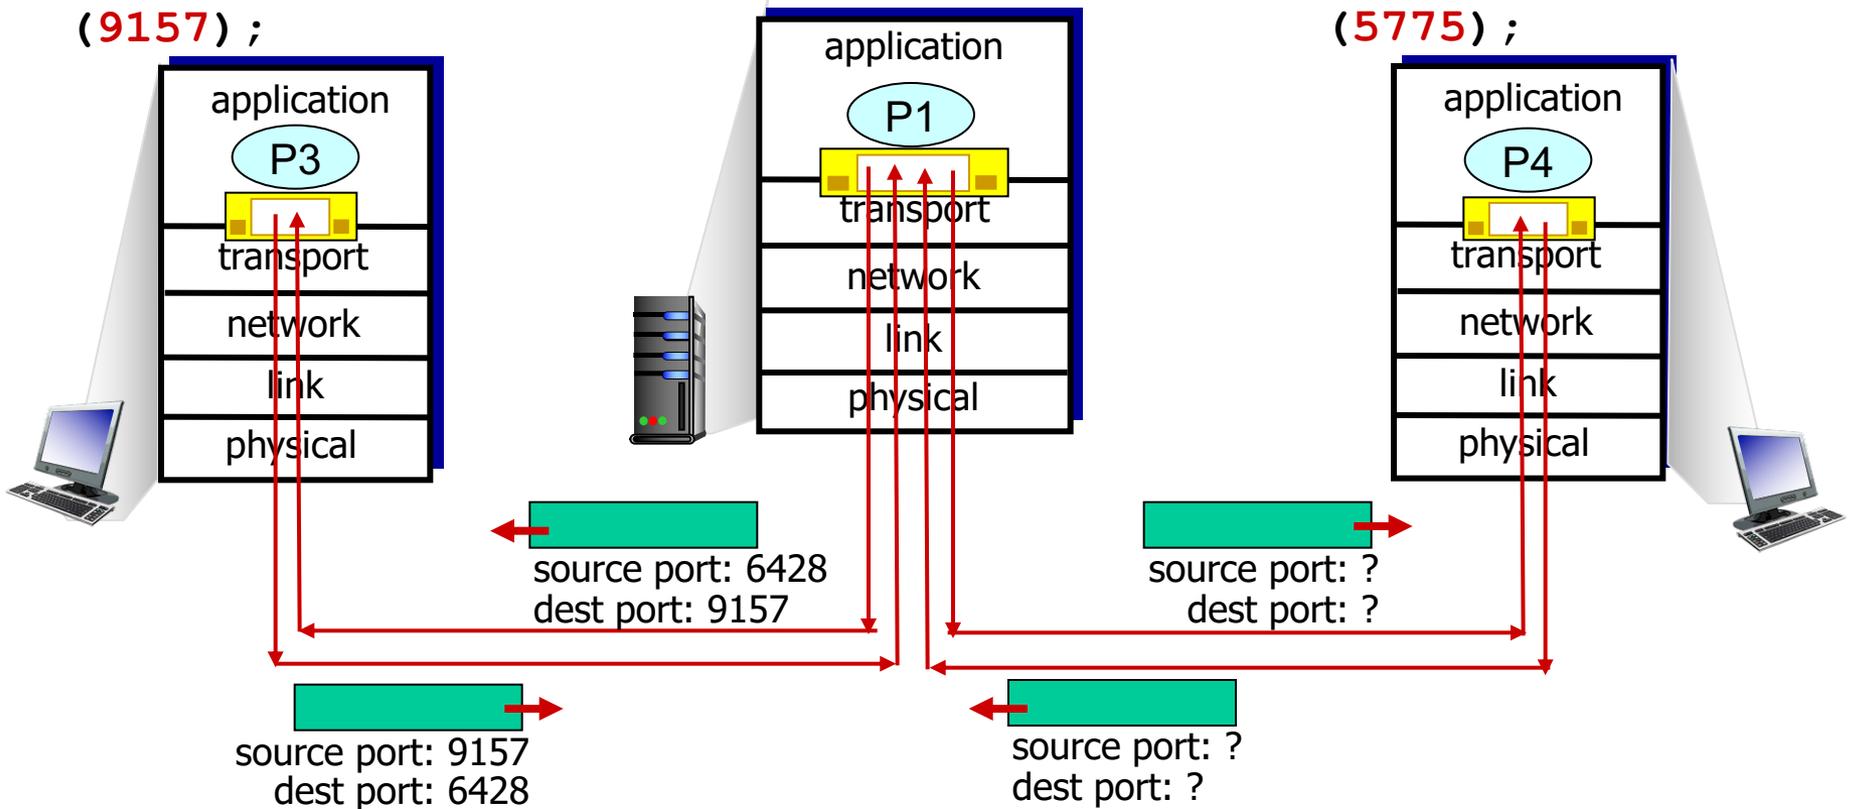

TCP/UDP segment format

# Connectionless demux: example

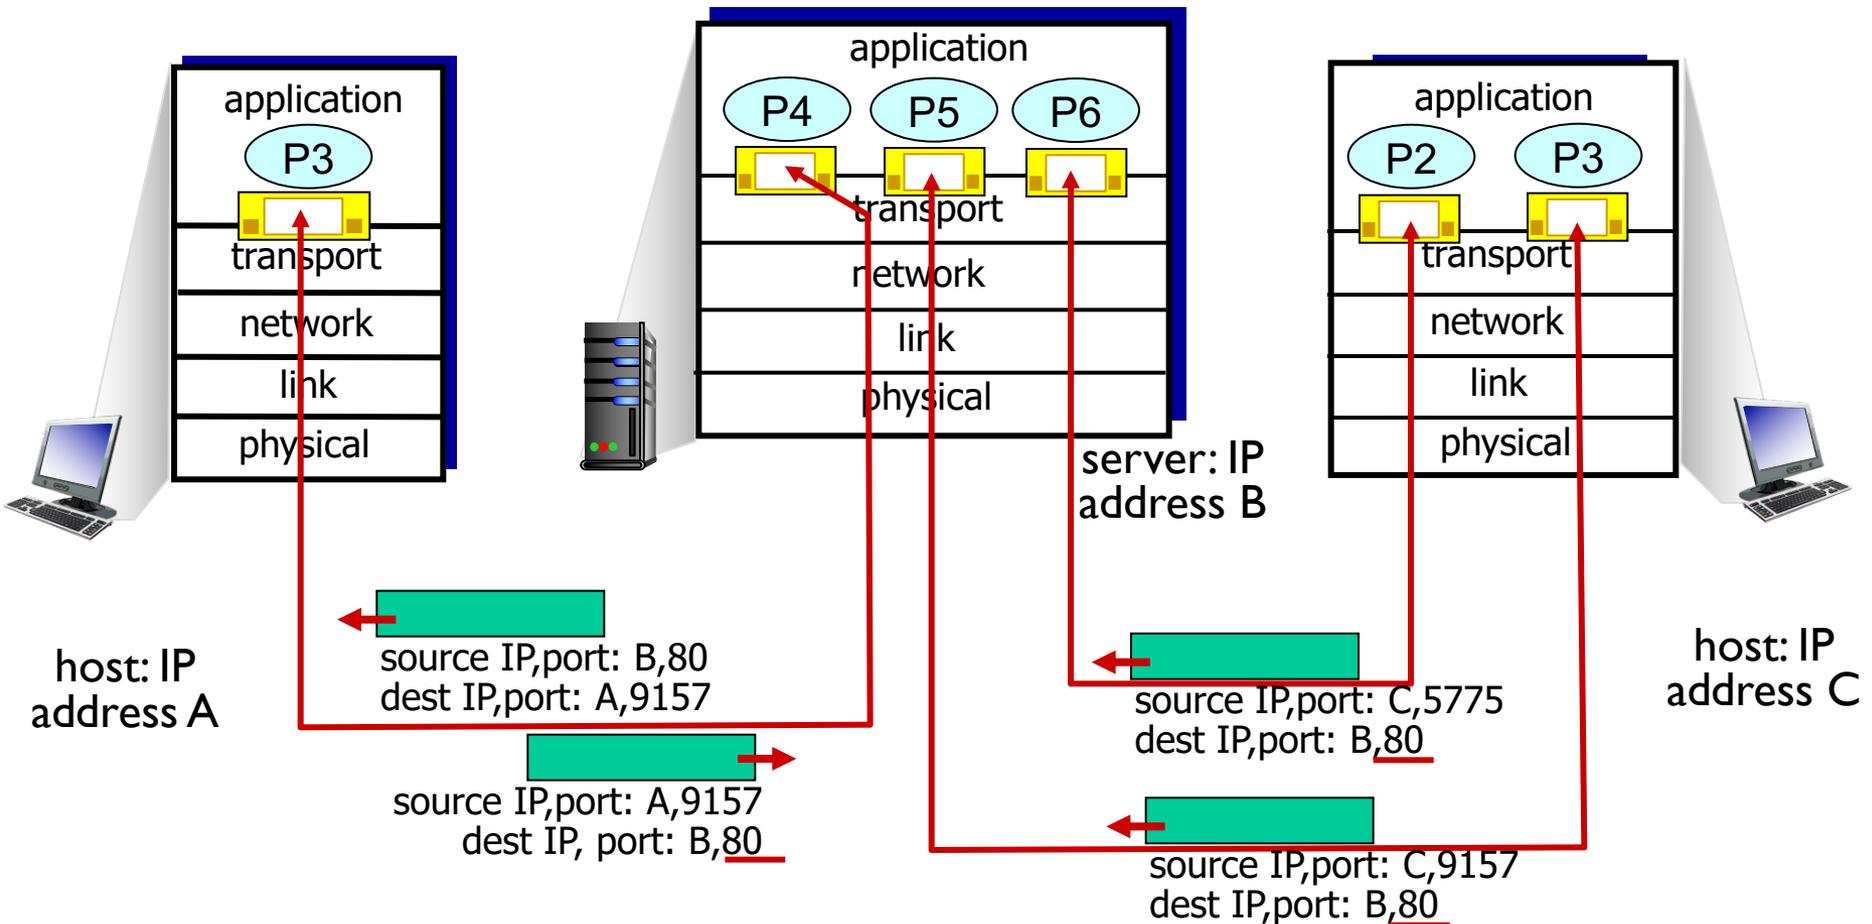

```
DatagramSocket  
mySocket2 = new  
DatagramSocket  
(9157);
```

```
DatagramSocket  
serverSocket = new  
DatagramSocket  
(6428);
```

```
DatagramSocket  
mySocket1 = new  
DatagramSocket  
(5775);
```

# Connection-oriented demux: example

three segments, all destined to IP address: B,  
dest port: 80 are demultiplexed to *different* sockets

# Chapter 3 outline

3.1 transport-layer services

3.2 multiplexing and demultiplexing

**3.3 connectionless transport: UDP**

3.4 principles of reliable data transfer

3.5 connection-oriented transport: TCP

- segment structure
- reliable data transfer
- flow control
- connection management

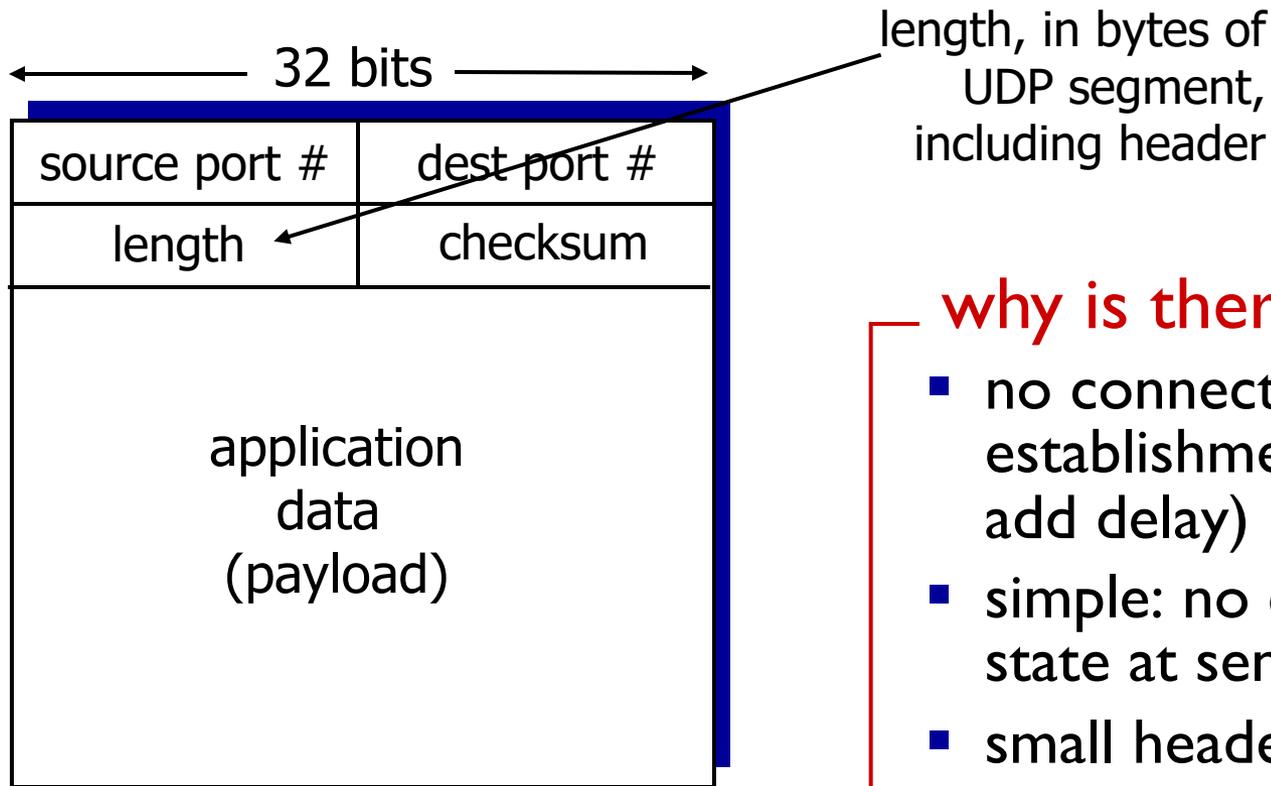

3.6 principles of congestion control

3.7 TCP congestion control

# UDP: User Datagram Protocol [RFC 768]

- “no frills,” “bare bones”  
Internet transport  
protocol
- “best effort” service, UDP  
segments may be:
  - lost
  - delivered out-of-order  
to app
- *connectionless*:
  - no handshaking  
between UDP sender,  
receiver
  - each UDP segment  
handled independently  
of others
- UDP use:
  - streaming multimedia  
apps (loss tolerant, rate  
sensitive)
  - DNS
  - SNMP
- reliable transfer over  
UDP:
  - add reliability at  
application layer
  - application-specific error  
recovery!

# UDP: segment header

UDP segment format

## why is there a UDP?

- no connection establishment (which can add delay)
- simple: no connection state at sender, receiver
- small header size
- no congestion control: UDP can blast away as fast as desired

# UDP checksum

*Goal:* detect “errors” (e.g., flipped bits) in transmitted segment

## sender:

- treat segment contents, including header fields, as sequence of 16-bit integers
- checksum: addition (one’s complement sum) of segment contents
- sender puts checksum value into UDP checksum field

## receiver:

- compute checksum of received segment
- check if computed checksum equals checksum field value:
  - NO - error detected
  - YES - no error detected.  
*But maybe errors nonetheless? More later*
- ....

# Internet checksum: example

example: add two 16-bit integers

	1 1 1 0 0 1 1 0 0 1 1 0 0 1 1 0
	1 1 0 1 0 1 0 1 0 1 0 1 0 1 0 1
<hr/>	
wraparound	1 1 0 1 1 1 0 1 1 1 0 1 1 1 0 1 1
<hr/>	
sum	1 0 1 1 1 0 1 1 1 0 1 1 1 1 0 0
checksum	0 1 0 0 0 1 0 0 0 1 0 0 0 0 1 1

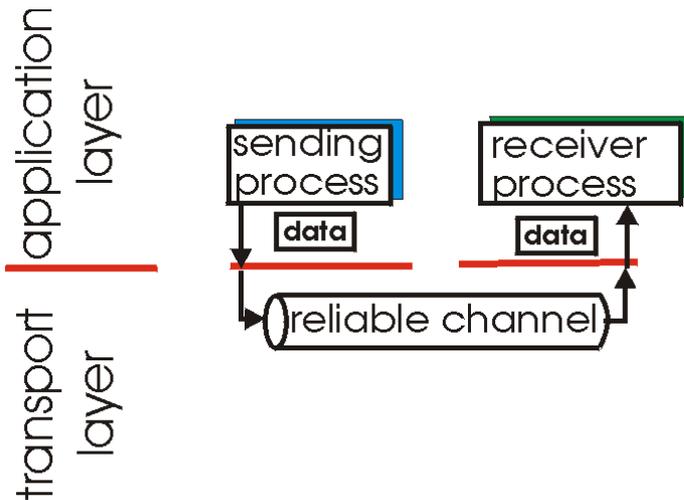

*Note:* when adding numbers, a carryout from the most significant bit needs to be added to the result

# Chapter 3 outline

- 3.1 transport-layer services
- 3.2 multiplexing and demultiplexing
- 3.3 connectionless transport: UDP
- 3.4 principles of reliable data transfer

# Principles of reliable data transfer

- important in application, transport, link layers
  - top-10 list of important networking topics!

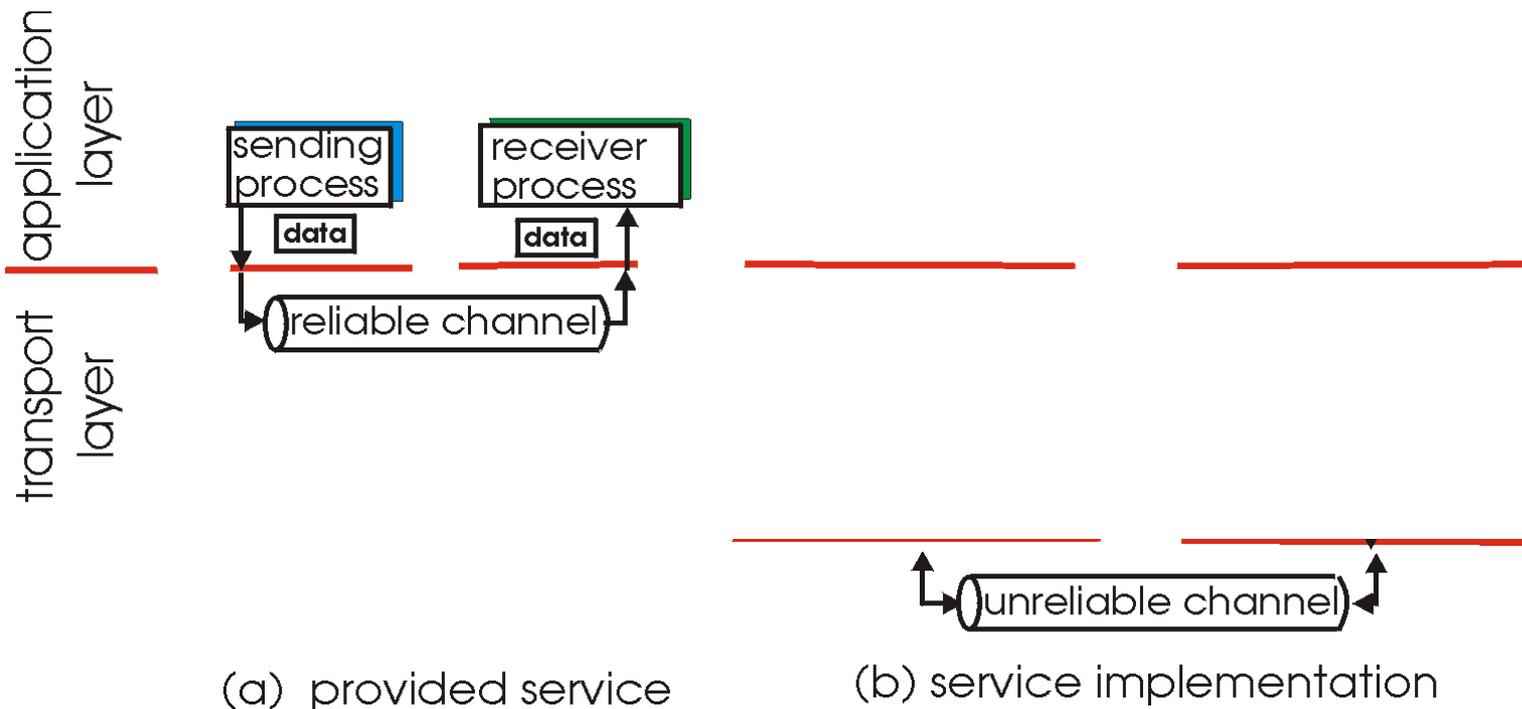

(a) provided service

- characteristics of unreliable channel will determine complexity of reliable data transfer protocol (rdt)

# Principles of reliable data transfer

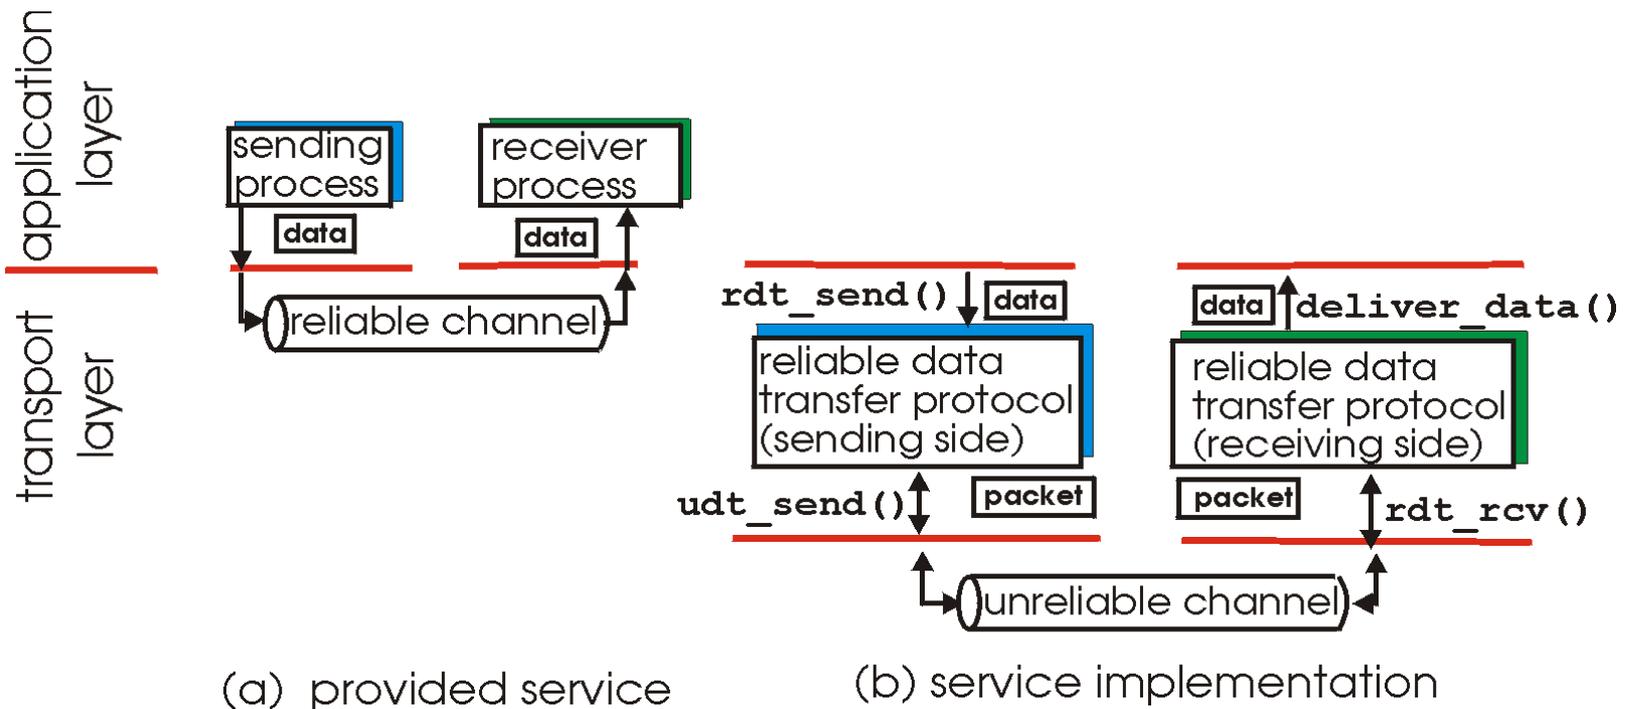

- important in application, transport, link layers
  - top-10 list of important networking topics!

- characteristics of unreliable channel will determine complexity of reliable data transfer protocol (rdt)

# Principles of reliable data transfer

- important in application, transport, link layers
  - top-10 list of important networking topics!

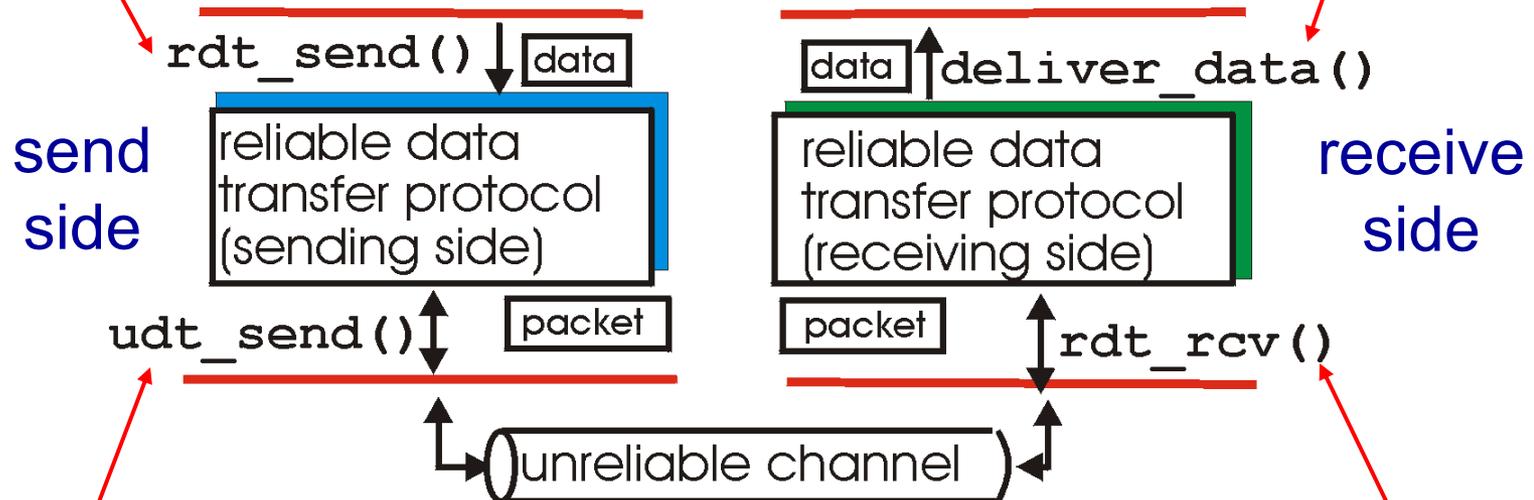

- characteristics of unreliable channel will determine complexity of reliable data transfer protocol (rdt)

# Reliable data transfer: getting started

**rdt\_send()** : called from above, (e.g., by app.). Passed data to deliver to receiver upper layer

**deliver\_data()** : called by **rdt** to deliver data to upper

**udt\_send()** : called by rdt, to transfer packet over unreliable channel to receiver

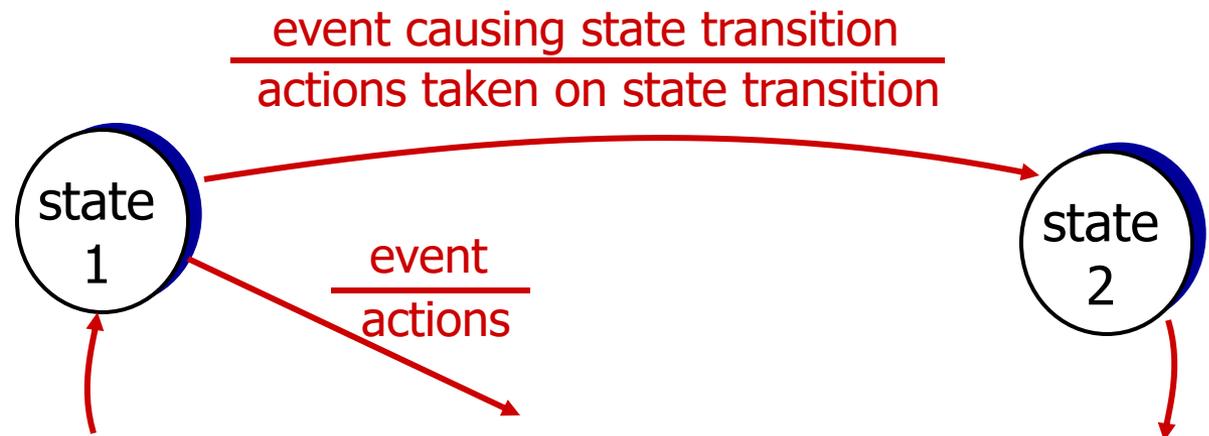

**rdt\_rcv()** : called when packet arrives on rcv-side of channel

# Reliable data transfer: getting started

we' ll:

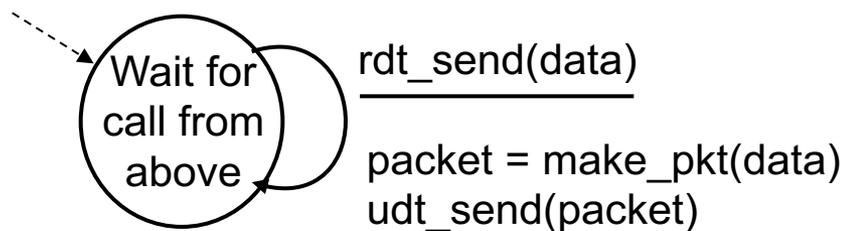

- incrementally develop sender, receiver sides of reliable data transfer protocol (rdt)
- consider only unidirectional data transfer
  - but control info will flow on both directions!
- use finite state machines (FSM) to specify sender, receiver

**state:** when in this “state” next state uniquely determined by next event

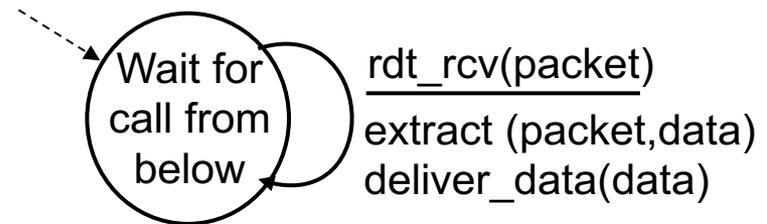

# rdt 1.0: reliable transfer over a reliable channel

- underlying channel perfectly reliable
  - no bit errors
  - no loss of packets
- separate FSMs for sender, receiver:
  - sender sends data into underlying channel
  - receiver reads data from underlying channel

sender

receiver

# rdt2.0: channel with bit errors

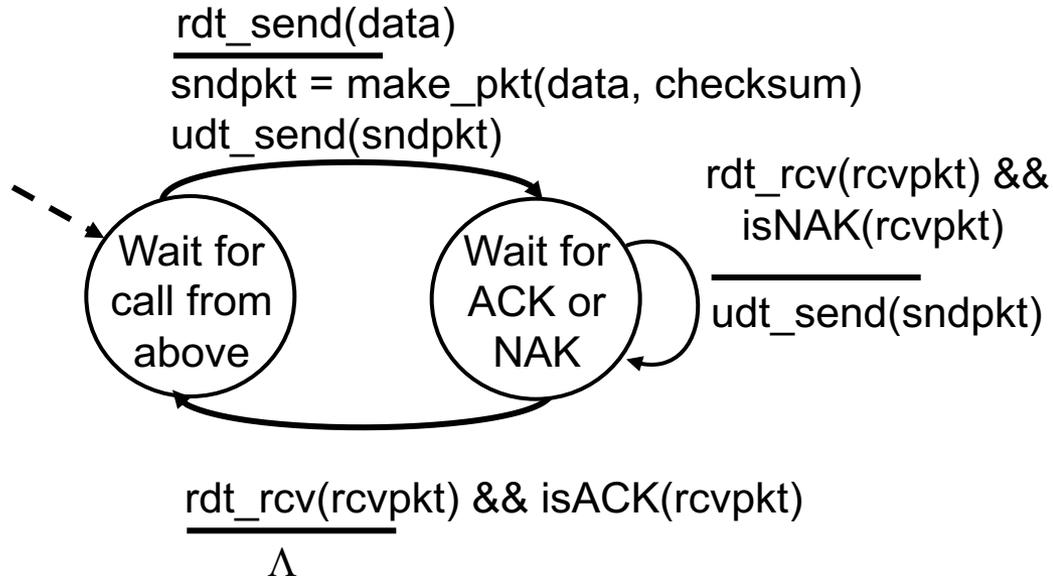

- underlying channel may flip bits in packet
  - checksum to detect bit errors
- *the question*: how to recover from errors:

*How do humans recover from “errors”  
during conversation?*

# rdt2.0: channel with bit errors

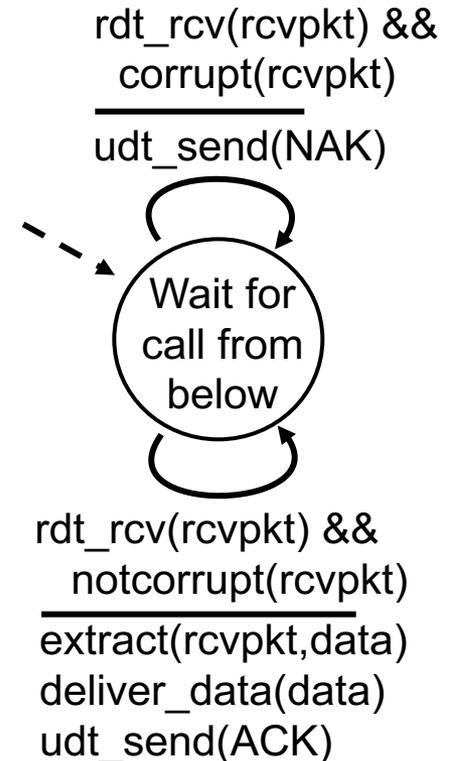

- underlying channel may flip bits in packet
  - checksum to detect bit errors
- *the question*: how to recover from errors:
  - *acknowledgements (ACKs)*: receiver explicitly tells sender that pkt received OK
  - *negative acknowledgements (NAKs)*: receiver explicitly tells sender that pkt had errors
  - sender retransmits pkt on receipt of NAK
- new mechanisms in `rdt2.0` (beyond `rdt1.0`):
  - error detection
  - feedback: control msgs (ACK,NAK) from receiver to sender

# rdt2.0: FSM specification

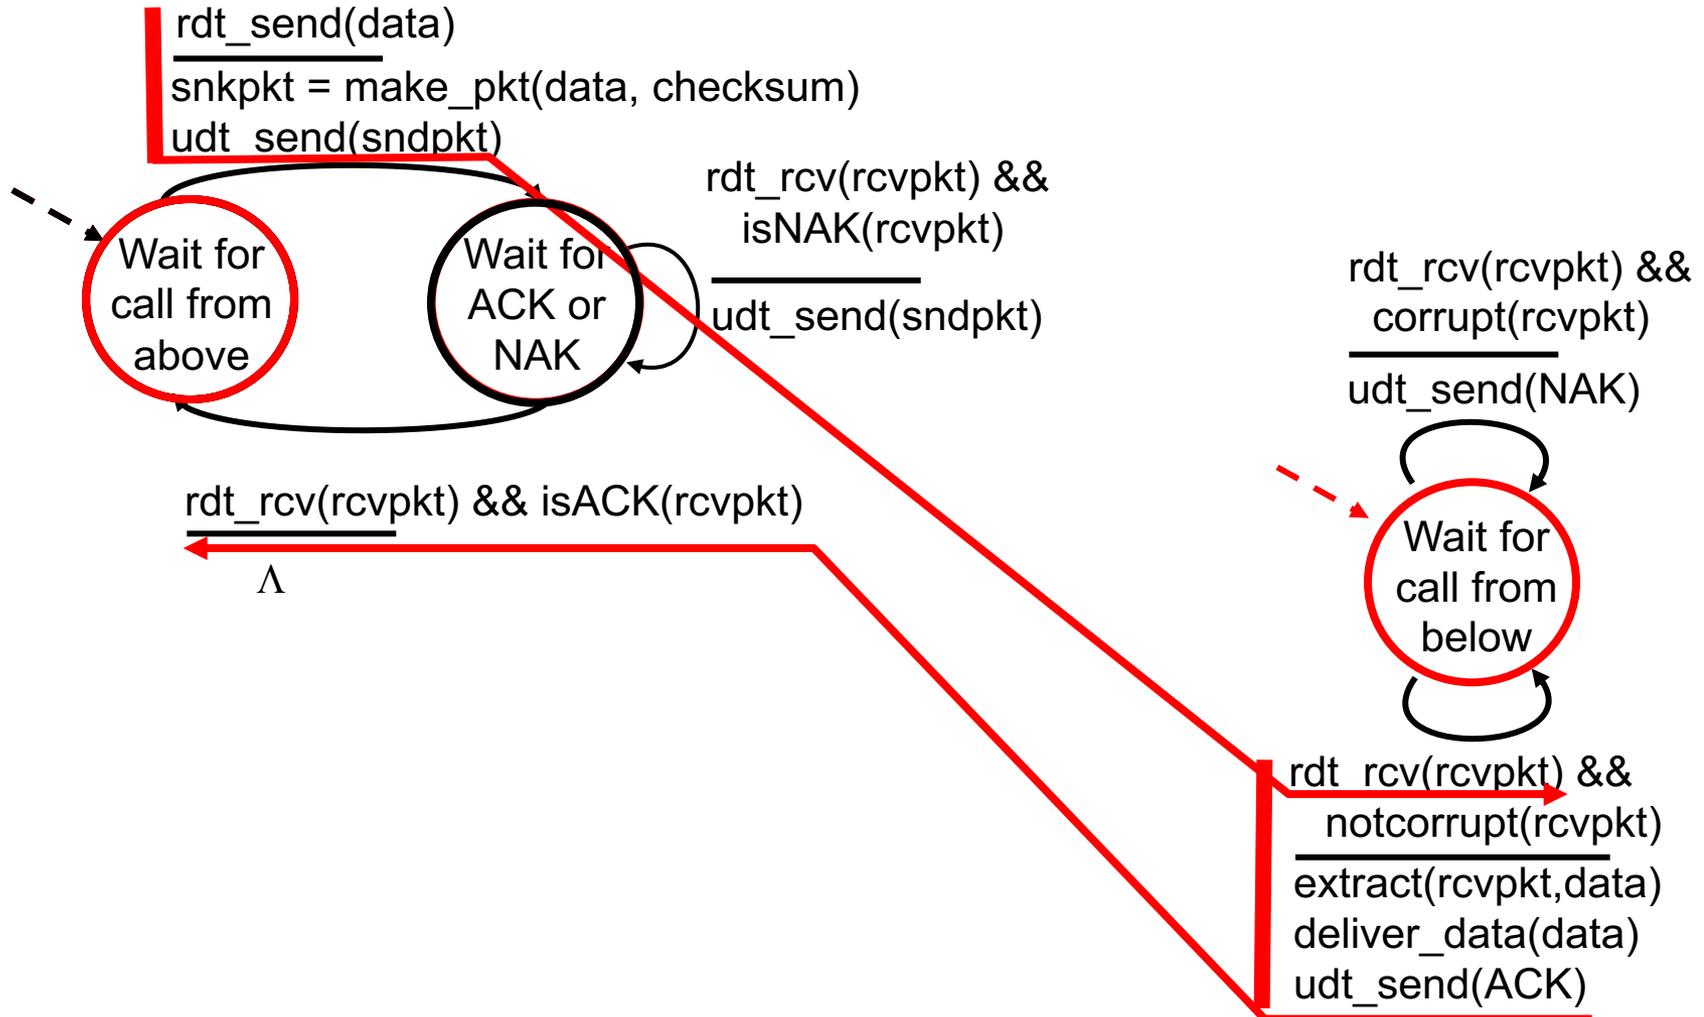

sender

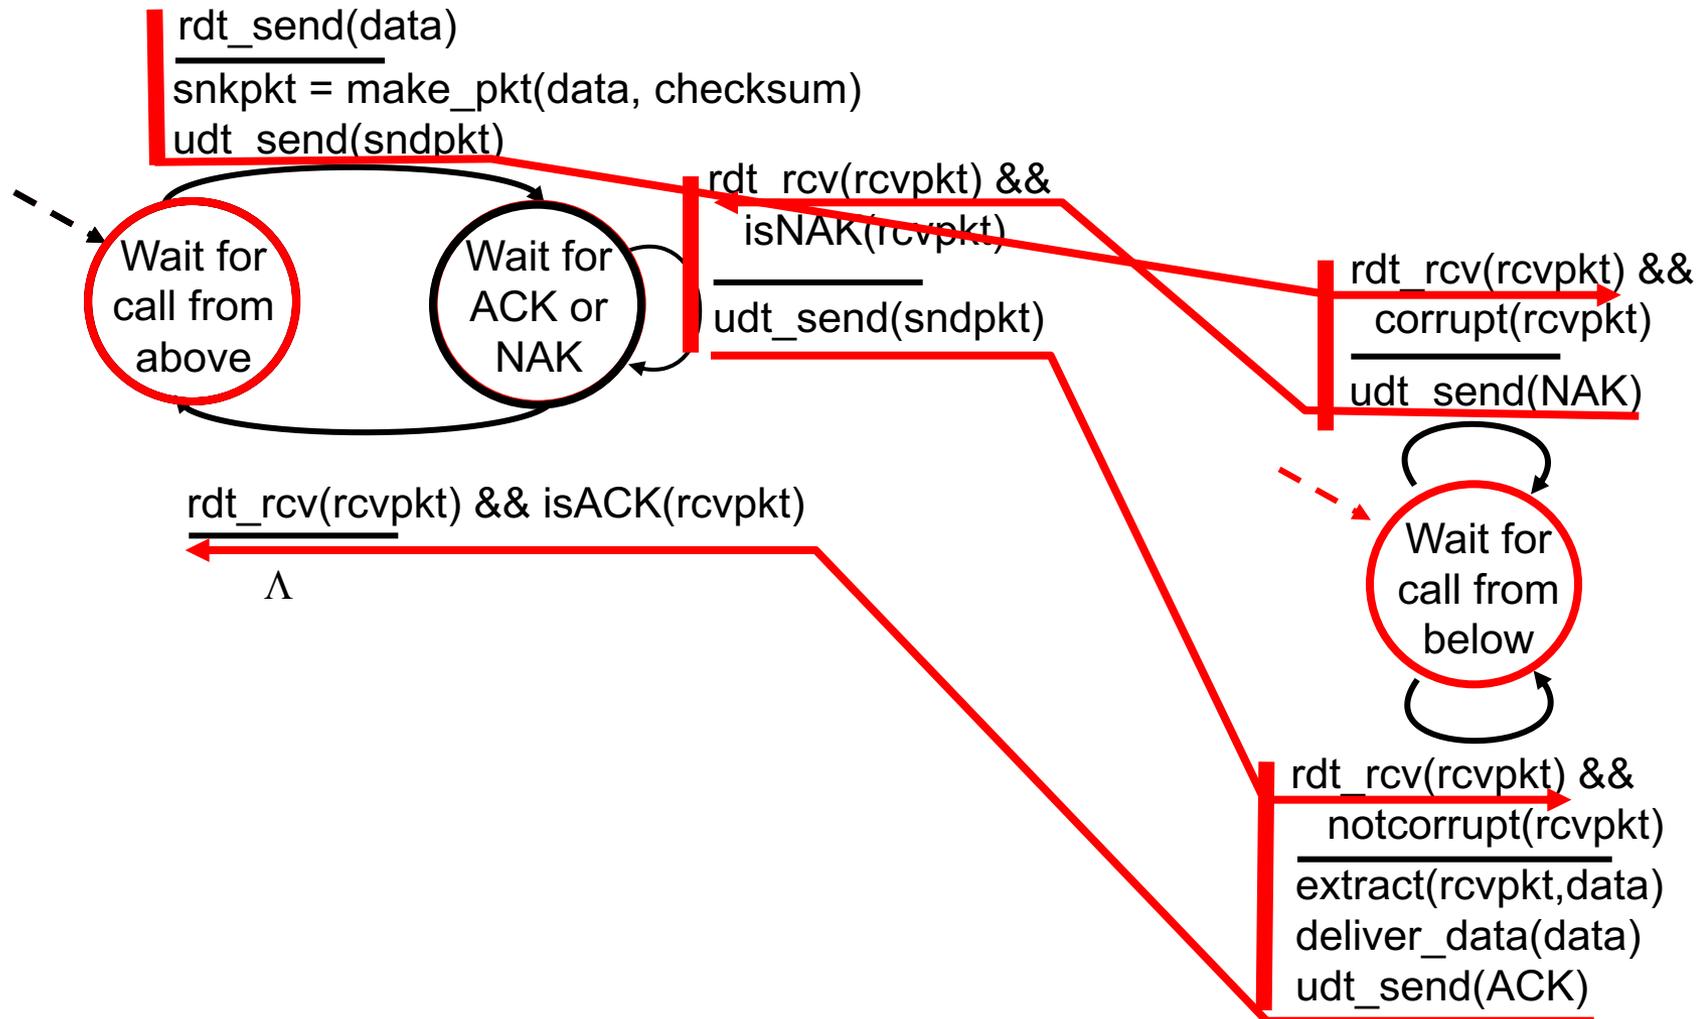

receiver

# rdt2.0: operation with no errors

# rdt2.0: error scenario

# rdt2.0 has a fatal flaw!

## what happens if ACK/NAK corrupted?

- sender doesn't know what happened at receiver!
- can't just retransmit: possible duplicate

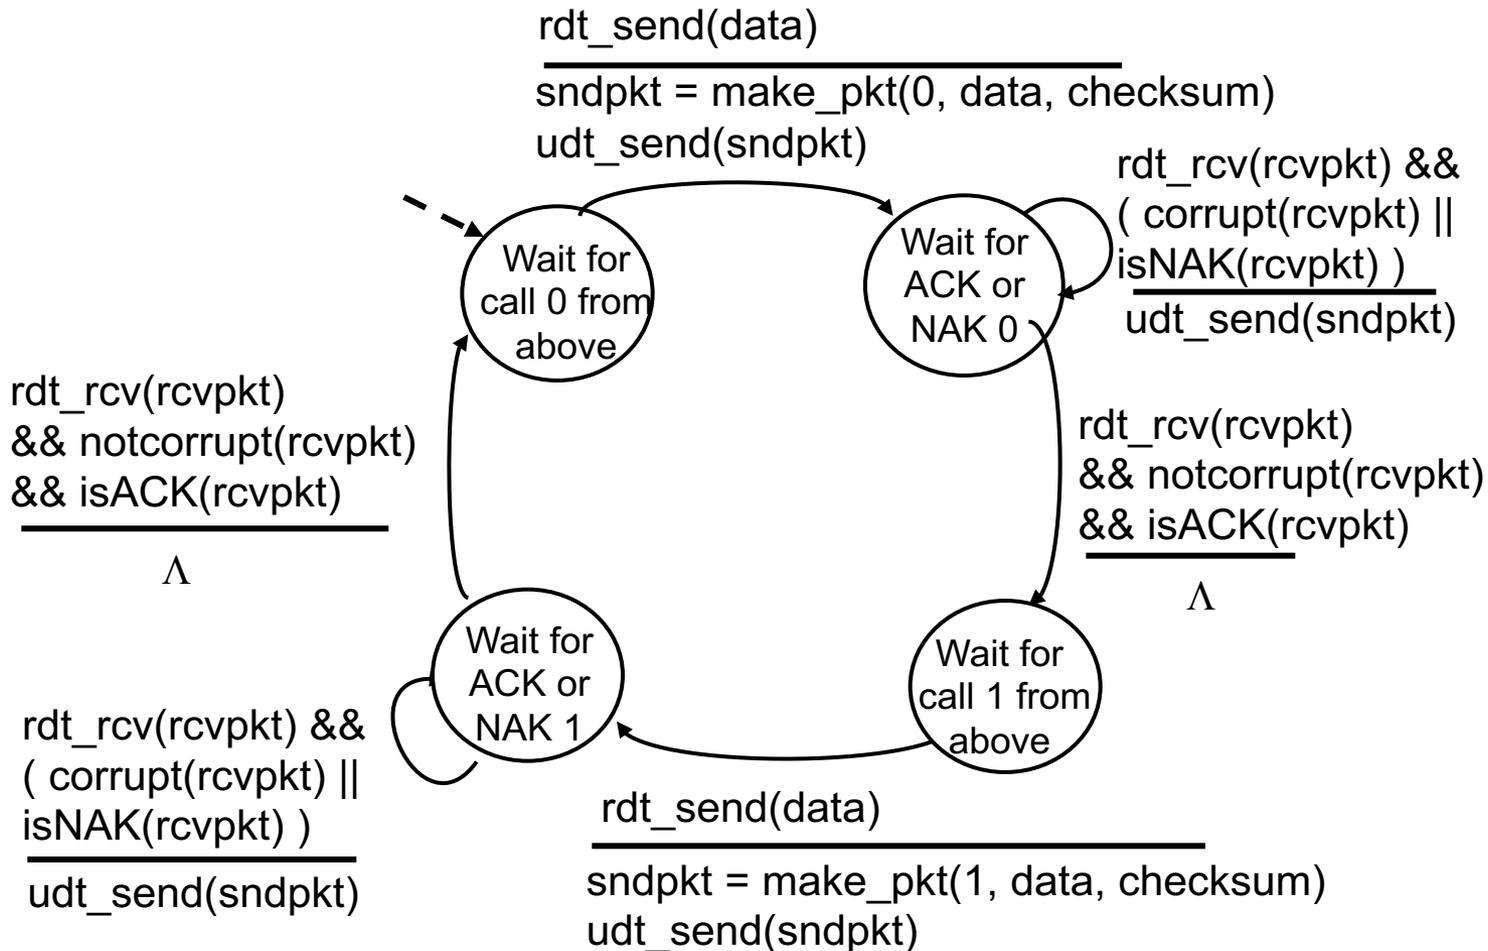

## handling duplicates:

- sender retransmits current pkt if ACK/NAK corrupted
- sender adds *sequence number* to each pkt
- receiver discards (doesn't deliver up) duplicate pkt

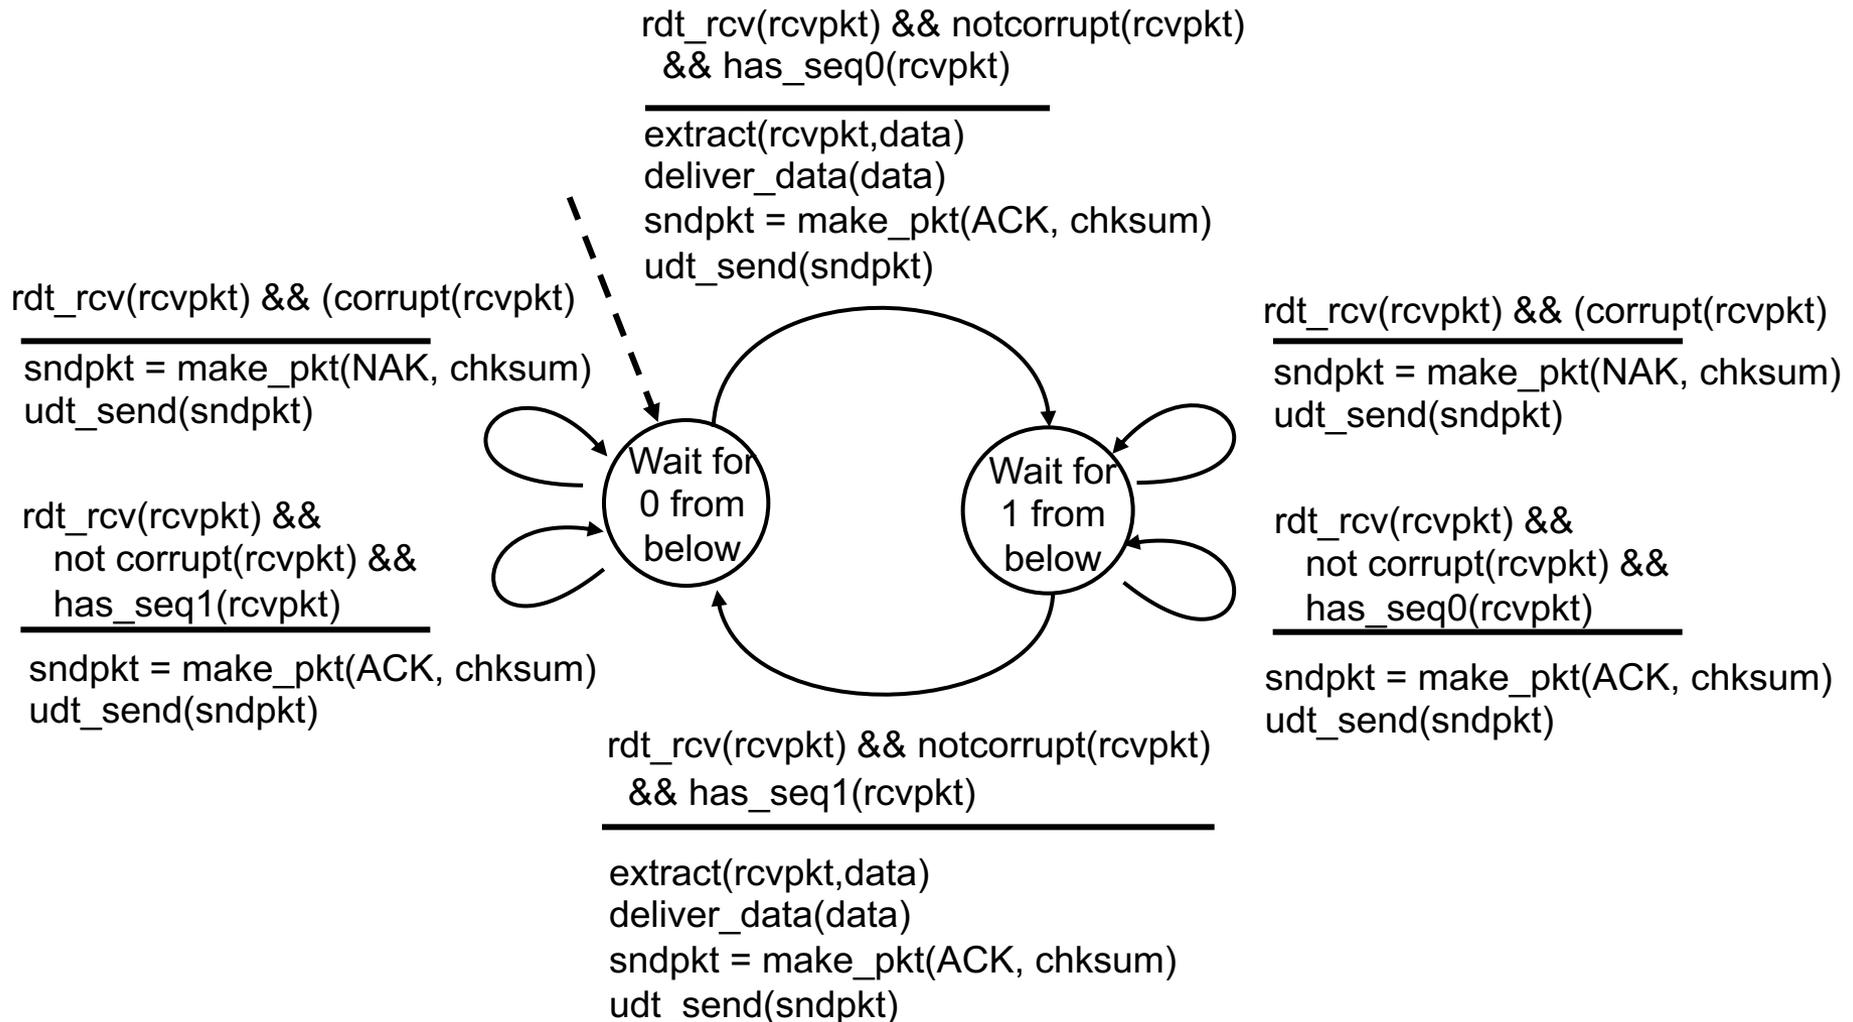

## stop and wait

sender sends one packet,  
then waits for receiver  
response

# rdt2.1: sender, handles garbled ACK/NAKs

# rdt2.1: receiver, handles garbled ACK/NAKs

# rdt2.1: discussion

## sender:

- seq # added to pkt
- two seq. #'s (0,1) will suffice. Why?
- must check if received ACK/NAK corrupted
- twice as many states
  - state must “remember” whether “expected” pkt should have seq # of 0 or 1

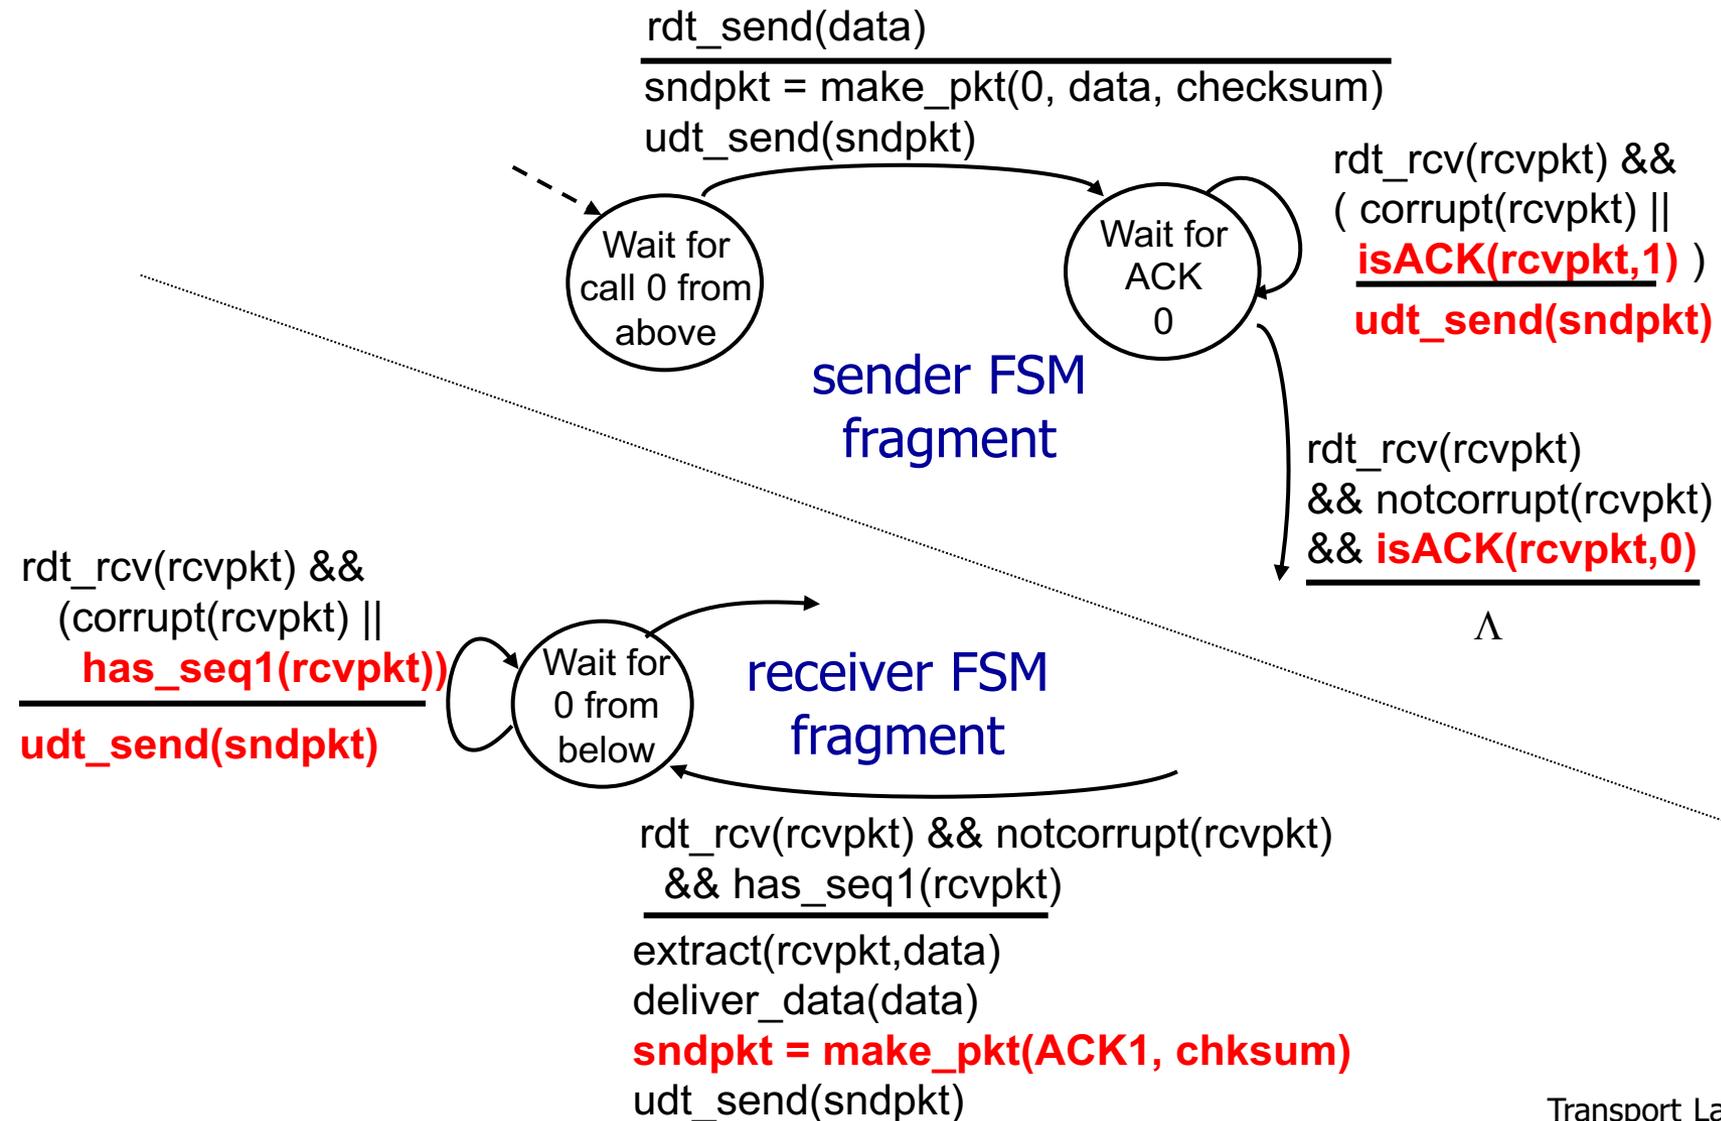

## receiver:

- must check if received packet is duplicate
  - state indicates whether 0 or 1 is expected pkt seq #
- note: receiver can *not* know if its last ACK/NAK received OK at sender

# rdt2.2: a NAK-free protocol

- same functionality as rdt2.1, using ACKs only
- instead of NAK, receiver sends ACK for last pkt received OK
  - receiver must *explicitly* include seq # of pkt being ACKed
- duplicate ACK at sender results in same action as NAK: *retransmit current pkt*

# rdt2.2: sender, receiver fragments

# rdt3.0: channels with errors and loss

## new assumption:

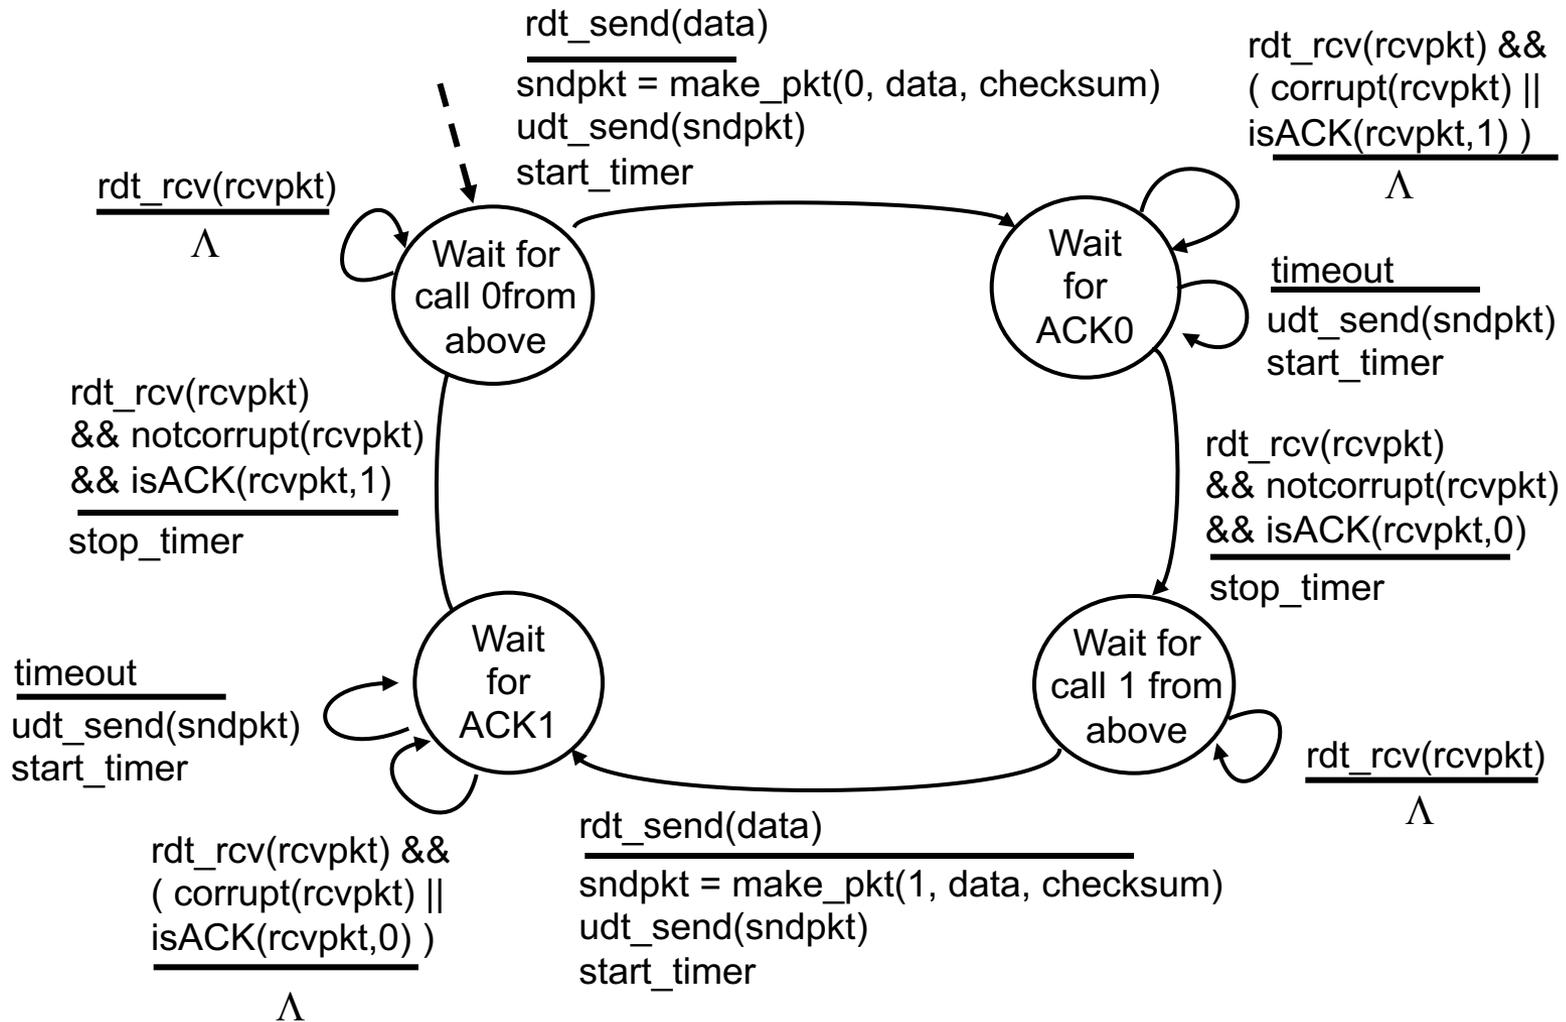

underlying channel can also lose packets (data, ACKs)

- checksum, seq. #, ACKs, retransmissions will be of help ... but not enough

approach: sender waits “reasonable” amount of time for ACK

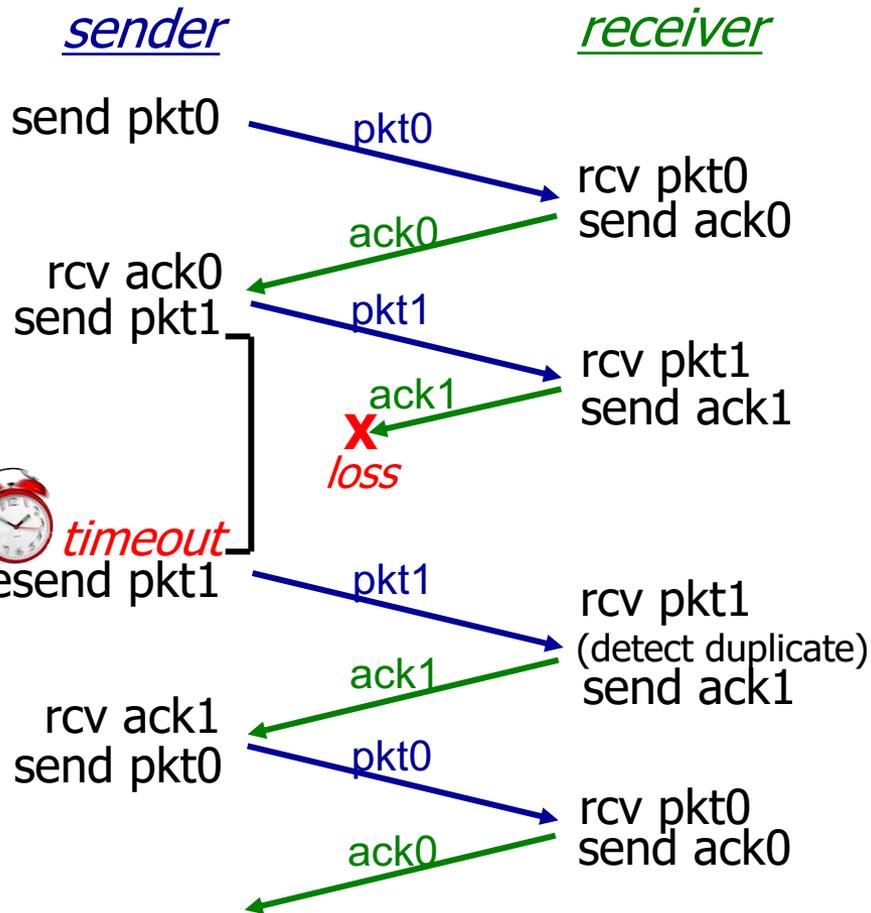

- retransmits if no ACK received in this time
- if pkt (or ACK) just delayed (not lost):
  - retransmission will be duplicate, but seq. #'s already handles this
  - receiver must specify seq # of pkt being ACKed
- requires countdown timer

# rdt3.0 sender

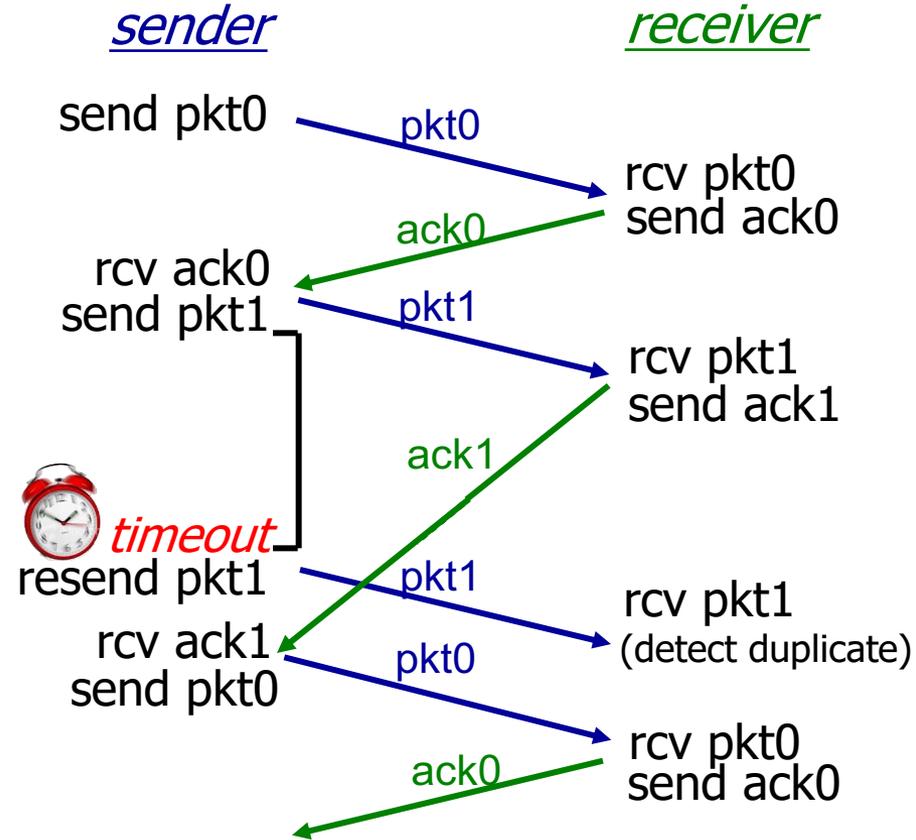

# rdt3.0 in action

(c) ACK loss

(d) premature timeout/ delayed ACK

# Performance of rdt3.0

- rdt3.0 is correct, but performance stinks
- e.g.: 1 Gbps link, 15 ms prop. delay, 8000 bit packet:

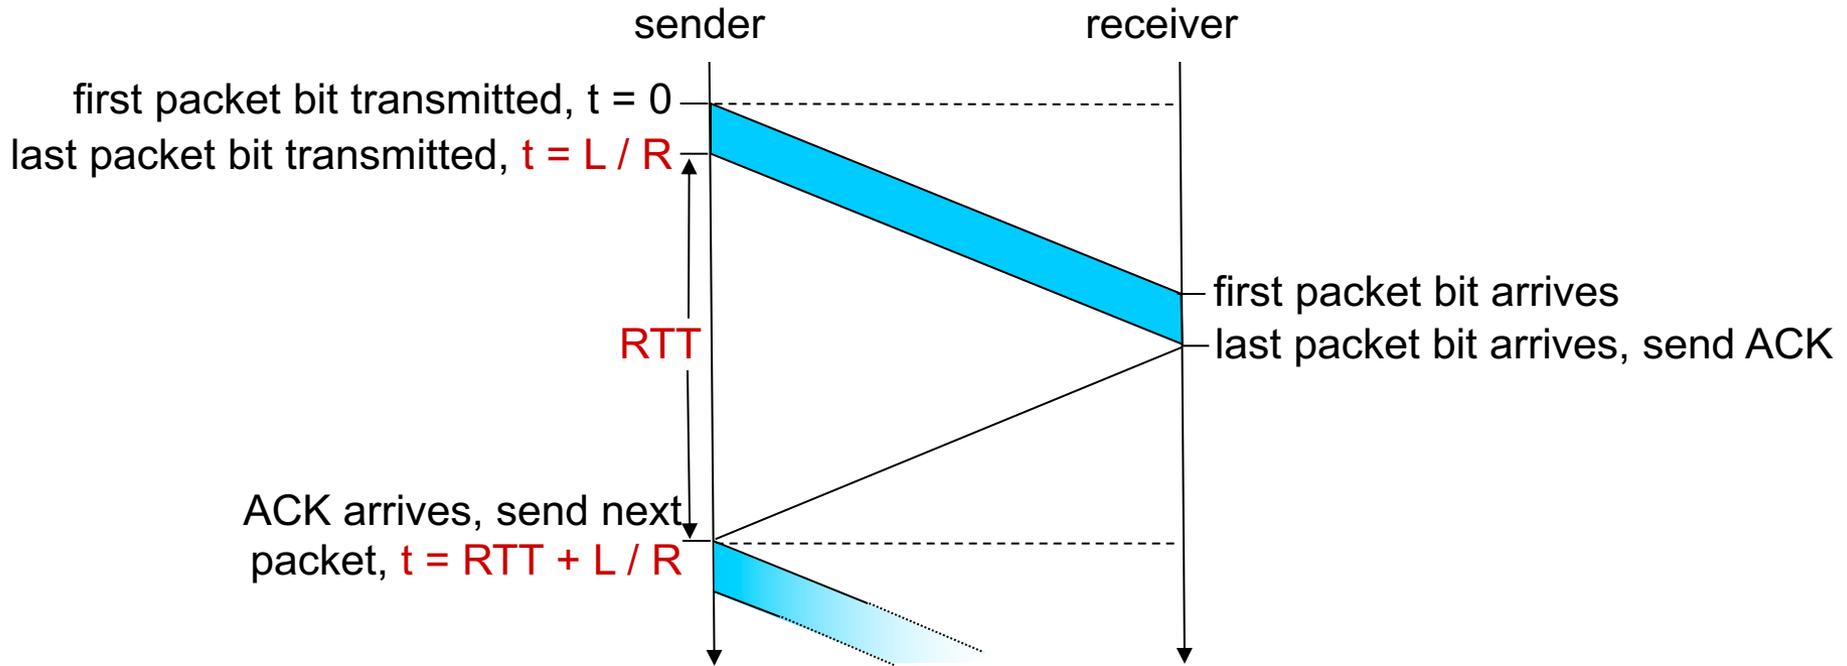

$$D_{trans} = \frac{L}{R} = \frac{8000 \text{ bits}}{10^9 \text{ bits/sec}} = 8 \text{ microseconds}$$

- $U_{sender}$ : *utilization* – fraction of time sender busy sending

$$U_{sender} = \frac{L/R}{RTT + L/R} = \frac{.008}{30.008} = 0.00027$$

- if RTT=30 msec, 1KB pkt every 30 msec: 33kB/sec thruput over 1 Gbps link
- network protocol limits use of physical resources!

# rdt3.0: stop-and-wait operation

$$U_{sender} = \frac{L/R}{RTT + L/R} = \frac{.008}{30.008} = 0.00027$$
